Nederlandse samenvatting –Summary in Dutch–

¹⁴⁴ Le resume en Neerlandais (j'aurais peut-être pu apprendre la langue juste pour ça...).

¹⁴³

English summary

¹⁴⁶ Le meme résume mais en Anglais (on commencera par la hein!).

List of Figures

147

148	2.1	Through the gold foil experiment Rutherford could show that most of the mass of atoms was contained in a positively charged nucleus and could then propose a more accurate atomic model than that of Thomson.	2-3
149	2.2	Figure 2.2a: Meson octet. Figure 2.2b: Baryon octet. Figure 2.2c: Baryon decuplet.	2-8
150	2.3	The elementary particles of the Standard Model are showed along with their names and properties. Their interactions with the strong, weak and electromagnetic forces have been explicated using color squares. In the left column, the scalar higgs boson is depicted, while the central is focused on the matter particles, the fermions, and the right on the force carriers, the gauge bosons. The role of the Higgs boson in electroweak symmetry breaking is highlighted, and the corresponding way properties of the various particles differ in the (high-energy) symmetric phase (top) and the (low-energy) broken-symmetry phase (bottom) are showed.	2-11
151	2.4	CERN accelerator complex.	2-15
152	2.5	Pictures of the different accelerators. From top to bottom: first the LINAC 2 and the <i>Pb</i> source of LINAC 3. Then the Booster and the LEIR. Finally, the PS, the SPS and the LHC.	2-16
153	2.6	Figure 2.6a: schematics of the LHC cryodipoles. 1: Superconducting Coils, 2: Beam pipe, 3: Heat exchanger Pipe, 4: Helium-II Vessel, 5: Superconducting Bus-bar, 6: Iron Yoke, 7: Non-Magnetic Collars, 8: Vacuum Vessel, 9: Radiation Screen, 10: Thermal Shield, 11: Auxiliary Bus-bar Tube, 12: Instrumentation Feed Throughs, 13: Protection Diode, 14: Quadrupole Bus-bars, 15: Spool Piece Bus-bars. Figure 2.6b: magnetic field and resulting motion force applied on the beam particles.	2-17
154	2.7	Figure 2.7a: picture of the LHC quadrupoles. Figure 2.7b: magnetic fields and resulting focussing force applied on the beam by 2 consecutive quadrupoles.	2-18
155	2.8	Picture of the CMS barrel. The red outer layer is the muon system hosted into the red iron return yokes. The calorimeters are the blue cylinder inside in magnet solenoid and the tracker is the inner yellow cylinder built around the beam pipe.	2-19
156	2.9	View of the CMS apparatus and of its different components.	2-19
157	2.10	Slice showing CMS sub-detectors and how particles interact with them.	2-20
158	2.11	CMS tracker.	2-20
159	2.12	Figure 2.12a: picture of the ECAL. Figure 2.12b: picture of the lead tungstate crystals composing the ECAL.	2-21
160	2.13	CMS hadron calorimeter barrel.	2-21
161	2.14	A quadrant of the muon system, showing DTs (yellow), RPCs (blue), and CSCs (green).	2-22
162	2.15	Figure 2.15a: Barrel wheel with its detector rings and return yokes. Figure 2.15b: CSC endcap disk with the 2 CSC stations. The outer station is made of 10 deg detectors while the inner station is made of 20 deg detectors. Figure 2.15c: RPC endcap disk. The inner station is not equipped and the inner CSC station can be seen.	2-23

- 187 2.16 Figure 2.16a: Cross section of a DT module showing the two superlayers measur-
 188 ing the ϕ coordinate, perpendicular to the cross section plane, and the superlayer
 189 measuring the η coordinate, placed in between the two others with honeycomb and
 190 parallel to the cross section plane. The DT detector is sandwiched in between 2
 191 RPCs whose readout strips are perpendicular to the cross section plane, measuring
 192 the ϕ coordinate. Figure 2.16b: A DT cell is shown together with its electric field.
 193 The path of a muon through a superlayer is shown. 2-23
- 194 2.17 Figure 2.17a: cathode strips and anode wire layout of a CSC panel. Figure 2.17b
 195 avalanche development and charge collection by anode wires and induction on cath-
 196 ode strips inside of a CSC panel. 2-24
- 197 2.18 Muon track reconstruction through the 6 panels of a CMS CSC using the infor-
 198 mation of anode wire groups and cathode strip charge distribution combined with
 199 comparator bits to decide on which half strip the muon is more likely to have passed. 2-24
- 200 2.19 Double gap layout of CMS RPCs. Muons passing through the gas volumes will cre-
 201 ate electron-ions pairs by ionising the gas. this ionisation will immediately translate
 202 into a developing avalanche. 2-25
- 203 3.1 Detailed timeline projection of for LHC and HL-LHC operation until 2039 show-
 204 ing the evolution of the instantaneous and integrated luminosity as designed (Fig-
 205 ure 3.1a) and in the ultimate case where the instantaneous luminosity is increased to
 206 $7.5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ (Figure 3.1b) [20, 22]. 3-2
- 207 3.2 Absorbed dose in the CMS cavern after an integrated luminosity of 3000 fb. Using
 208 the interaction point as reference, R is the transverse distance from the beamline and
 209 Z is the distance along the beamline. 3-3
- 210 3.3 A quadrant of the muon system, showing DTs (yellow), RPCs (blue), and CSCs
 211 (green). The locations of new forward muon detectors for Phase-II are contained
 212 within the dashed box and indicated in red for GEM stations (ME0, GE1/1, and
 213 GE2/1) and dark blue for improved RPC (iRPC) stations (RE3/1 and RE4/1). 3-4
- 214 3.4 Figure 3.4a: Extrapolated fraction of failing channels of the present DT MiC1 elec-
 215 tronics as a function of the integrated luminosity for different scenari until LS4. Fig-
 216 ure 3.4b: Comparison of the current (left) and upgraded (right) DT data processing.
 217 So far, the data is sent to service cavern of CMS facility via copper-to-optical-fiber
 218 translators (CuOF) by each MiC1. There, data including RPCs and outer hadron
 219 calorimeter is combined into trigger primitives (TPG) and transmitted by the Twin-
 220 Mux system to CMS Track Finder. The time-to-digital converter (TDC) data is col-
 221 lected and sent to the CMS data acquisition system (DAQ) by the micro read-out
 222 server (μ ROS). After the upgrade, the TDC data will be sent via optical links to
 223 a patch panel inside the experimental cavern by each MiC2, and transferred to the
 224 back-end, where triggering and event building will be performed. 3-6
- 225 3.5 Figure 3.5a: The event loss fractions as a function of the instantaneous luminosity is
 226 compared for CFEBs (Phase-1) and DCFEBs (Phase-II) at different CSC locations.
 227 HL-LHC luminosity is marked with the dashed brown line. Figure 3.5b: Comparison
 228 of the current (left) and upgraded (right) CSC data processing. A part of the con-
 229 nections in between ALCTs and DCFEBs, and the trigger mother boards (TMBs)
 230 and data acquisition mother boards (DMBs) will be upgraded toward optical data
 231 transfer. The detector dependent units (DDUs) used as interface in between CSCs'
 232 front-end electronics and the CMS DAQ will be replaced by new FED boards. 3-7
- 233 3.6 Comparison of the simulated time residuals in between reconstructed and true muon
 234 times without (blue) and with (red) the upgraded RPC link system. 3-8

235	3.7	RMS of the multiple scattering displacement as a function of muon p_T for the proposed forward muon stations. All of the electromagnetic processes such as bremsstrahlung and magnetic field effect are included in the simulation.	3-9
238	3.8	Simulation of the impact of RPC hit inclusion onto the local trigger primitive efficiency in station 3 (left) and station 4 (right). The contribution of iRPC starts above $ \eta = 1.8$	3-9
241	3.9	Expected hit rate due to neutrons, photons, electrons and positrons at HL-HLC instantaneous luminosity of $5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ in RE3/1 and RE4/1 chambers. The sensitivities of iRPCs used in the simulation for each particle are reported and differ from one endcap disk to another as the energies of the considered particles varies with the increasing distance from the interaction point.	3-10
246	3.10	Measured average charge per avalanche as a function of the effective electric field for different gas gap thickness in double gap RPCs using HPL electrodes.	3-11
248	3.11	The PETIROC time jitter as a function of the input signal amplitude, measured with and without internal clocks.	3-12
250	3.12	Schematics of a GEM showing the cathode on top, the GEM foil separating the gas volume into the drift region, in between the cathode and foil, and the induction region, in between the GEM foil and the anode, and the anode on which a 2D readout is installed. A negative voltage is applied on the cathode while the anode is connected to the ground.	3-13
255	3.13	Left: Picture of a CMS GEM foil provided by a scanning electron microscope. Right: Representation of the electric field lines in a GEM hole and of the amplification that electrons and ions undergo in the hole's volume due to the very intense electric field.	3-14
258	3.14	Schematic representation of CMS triple GEMs. The gas volume is divided into 4 areas. The drift area is the region where the primary electrons are created before being amplified a first time while passing through the first GEM foil. Then the process of drift and amplification is repeated twice in following two transfer areas and GEM foils. Finally, the charges have been amplified enough to induce current in the read-out strips while in the last drift area. The dimensions, potentials and electric fields are provided.	3-14
265	3.15	Simulated efficiency and rate of the standalone Level-1 muon trigger using tracks reconstructed in CSCs and all GEM stations compared with Phase-I values in the case where only CSCs are used or CSCs+GE1/1. The zones of inefficiency of the CSC subsystem are compensated by the addition of GEMs during Phase-II and the trigger rates is kept from increasing due to the high luminosity.	3-15
270	3.16	Figure 3.16a: Simulated resolution of the muon direction measurement $\Delta\phi$ with Phase-II conditions. In the second endcap station, the resolution is compared in the case of CSCs (ME2/1) alone and CSCs+GEMs (GE2/1+ME2/1) while a similar resolution measurement is given in the case of the first station (GE1/1+ME1/1). Figure 3.16b: The addition of GEM detectors on stations 1 and 2 (ME0 is considered to contribute to station station 1) as redundant system to CSCs allows to improve the muon momentum improvement through a more accurate measurement of the local bending angles ϕ_1 and ϕ_2	3-16
278	3.17	Schematics of the data communication chain for DAQ of the GEM subsystems. The sending of trigger data via optical links to the CSC OTMBs is only done for GE1/1 and GE2/1 to match the data with ME1/1 and ME2/1.	3-16

281	3.18	Figure 3.18a: Energy spectrum of GIF++ ^{137}Cs source as measured by the GE1/1 282 detector installed in GIF++. Figure 3.18b: Evolution of the normalized gain of the 283 GE1/1 detector installed at in GIF++ as a function of the integrated charge per unit 284 area. The first part of the study, up to a charge of 55 mC/cm^2 had been done in the 285 former Gamma Irradiation Facility (GIF) that has now been dismantled following 286 the construction of GIF++. No variation of the normalized gain can be observed 287 after an accumulation of 110 mC/cm^2	3-17
288	3.19	Figure 3.19a: Comparison of the gas gain as a function of the divider voltage before 289 and after the irradiation of a triple-GEM by neutrons in CHARM. Figure 3.19b: 290 Comparison of the gas gain as a function of the divider voltage before and after the 291 irradiation of a triple-GEM by alpha particles.	3-18
292	3.20	Data flow of the Level-1 Trigger during Phase-II operations.	3-20
293	4.1	Different phases of the avalanche development in the RPC gas volume subjected to 294 a constant electric field E_0 . a) An avalanche is initiated by the primary ionisation 295 caused by the passage of a charged particle through the gas volume. b) Due to 296 its growing size, the avalanche starts to locally influence the electric field. c) The 297 electrons, lighter than the cations reach the anode first. d) The ions reach the cathode. 298 While the charges have not recombined, the electric field in the small region around 299 the avalanche stays affected and locally blind the detector.	4-2
300	4.2	Effeciency (circles and stars with 30 mV and 100 mV thresholds respectively) and 301 streamer probability (opened circles) as function of the operating voltatge of a 2 mm 302 single gap HPL RPC flushed with a gas mixture containing (a) 5%, (b) 2%, (c) 1% 303 and (d) no SF_6 [39].	4-3
304	4.3	Movement of the charge carriers in an RPC. Figure 4.3a: Voltage across an RPC 305 whose electrode have a relative permittivity of 5 at the moment the tension s applied. 306 Figure 4.3b: After the charge carriers moved, the electrodes are charged and there 307 is no voltage drop over the electrodes anymore. The full potential is applied on the 308 gas gap only. Figure 4.3c: The streamer discharge initiated by a charged particle 309 transports electrons and cations towards the anode and cathode respectively.	4-5
310	4.4	Typical oscilloscope pulses in streamer mode (Figure 4.4a) and avalanche mode(Figure 4.4b). 311 In the case of streamer mode, the very small avalanche signal is visible.	4-5
312	4.5	Rate capability comparison for the streamer and avalanche mode of operation. An 313 order of magnitude in rate capability for a maximal efficiency drop of 10% is gained 314 by using the avalanche mode over the streamer mode.	4-6
315	4.6	Possible double-gap RPC layouts: a) "standard" 1D double-gap RPC, as used in 316 CMS experiment, where the anodes are facing each other and a 1D read-out plane 317 is sandwiched in between them, b) double read-out double-gap RPC as used in AT- 318 LAS experiment, where the cathodes are facing each other and 2 read-out planes are 319 used on the outer surfaces. This last layout can offer the possibility to use a 2D 320 reconstruction by using orthogonal read-out planes.	4-7
321	4.7	Comparison of performance of CMS double and single gap RPCs using cosmic 322 muons [50]. Figure 4.7a: Comparison of efficiency sigmoids. Figure 4.7b: Volt- 323 age distribution at 95% of maximum efficiency. Figure 4.7c: $\Delta_{10\%}^{90\%}$ distribution. . . .	4-7
324	4.8	Presentation of ALICE MRPC using $250 \mu\text{m}$ gas gaps, $620 \mu\text{m}$ outer glass electrodes 325 and $550 \mu\text{m}$ inner floating electrodes. More details on the labels are given in [51]. . .	4-8
326	4.9	Particle identification applied to electrons in the STAR experiment. The identifica- 327 tion is performed combining ToF and dE/dx measurements [56].	4-9

328	4.10 Comparison of the detector performance of ALICE ToF MRPC [57] at fixed applied voltage (in blue) and at fixed effective voltage (in red). The effective voltage is kept fixed by increasing the applied voltage accordingly to the current drawn by the detector.	4-9
329		
330		
331	4.11 Ratio between total induced and drifting charge have been simulated for single gap, double-gap and multigap layouts [58]. The total induced charge for a double-gap RPC is a factor 2 higher than for a multigap.	4-10
332		
333		
334	4.12 Charge spectra have been simulated for single gap, double-gap and multigap layouts [58]. It appears that when single gap shows a decreasing spectrum, double and multigap layouts exhibit a spectrum whose peak is detached from the origin. The detachment gets stronger as the number of gaps increases.	4-11
335		
336		
337		
338	4.13 The maximal theoretical efficiency is simulated for single gap, double-gap and multi-gap layouts [58] at a constant gap thickness of 2 mm and using an effective Townsend coefficient of 9 mm^{-1}	4-11
339		
340		
341	5.1 Signals from the RPC strips are shaped by the FEE described on Figure 5.1a. Output LVDS signals are then read-out by a TDC module connected to a computer or converted into NIM and sent to scalers. Figure 5.1b describes how these converted signals are put in coincidence with the trigger.	5-3
342		
343		
344		
345	5.2 Description of the principle of a CFD. A comparison of threshold triggering (left) and constant fraction triggering (right) is shown in Figure 5.2a. Constant fraction triggering is obtained thanks to zero-crossing technique as explained in Figure 5.2b. The signal arriving at the input of the CFD is split into three components. A first one is delayed and connected to the inverting input of a first comparator. A second component is connected to the noninverting input of this first comparator. A third component is connected to the noninverting input of another comparator along with a threshold value connected to the inverting input. Finally, the output of both comparators is fed through an AND gate.	5-4
346		
347		
348		
349		
350		
351		
352		
353		
354	5.3 Figure 5.3a: The integrated charge per region (Barrel, Endcap) is extrapolated to HL-LHC integrated luminosity (3000 fb^{-1}) using the data accumulated in 2016 in every HV channels. Figure 5.3b: The hit rate per region (Barrel, Endcap) is linearly extrapolated to HL-LHC highest instantaneous luminosity ($5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$) using the rate as a function of instantaneous luminosity recorded by RPCs in 2017 showing a linear dependence.	5-5
355		
356		
357		
358		
359		
360	5.4 Background Fluka simulation compared to 2016 Data at $L = 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ in the fourth endcap disk region. A mismatch in between simulation and data can be observed. [To be understood.]	5-6
361		
362		
363	5.5 Layout of the test beam zone called X5c GIF at CERN. Photons from the radioactive source produce a sustained high rate of random hits over the whole area. The zone is surrounded by 8 m high and 80 cm thick concrete walls. Access is possible through three entry points. Two access doors for personnel and one large gate for material. A crane allows installation of heavy equipment in the area.	5-7
364		
365		
366		
367		
368	5.6 ^{137}Cs decays by β^- emission to the ground state of ^{137}Ba (BR = 5.64%) and via the 662 keV isomeric level of ^{137}Ba (BR = 94.36%) whose half-life is 2.55 min.	5-8
369		
370	5.7 Floor plan of the GIF++ facility. When the facility downstream of the GIF++ takes electron beam, a beam pipe is installed along the beam line (z-axis). The irradiator can be displaced laterally (its center moves from $x = 0.65 \text{ m}$ to 2.15 m), to increase the distance to the beam pipe.	5-8
371		
372		
373		
374	5.8 Simulated unattenuated current of photons in the xz plane (Figure 5.8a) and yz plane (Figure 5.8b) through the source at $x = 0.65 \text{ m}$ and $y = 0 \text{ m}$. With angular correction filters, the current of 662 keV photons is made uniform in xy planes.	5-9
375		
376		

377	5.9	Description of the RPC setup. Dimensions are given in mm. A tent containing RPCs is placed at 1720 mm from the source container. The source is situated in the center of the container. RE-4-2-BARC-161 chamber is 160 mm inside the tent. This way, the distance between the source and the chambers plan is 2060 mm. Figure 5.9a provides a side view of the setup in the xz plane while Figure 5.9b shows a top view in the yz plane.	5-10
383	5.10	RE-4-2-BARC-161 chamber is inside the tent as described in Figure 5.9. In the top right, the two scintillators used as trigger can be seen. This trigger system has an inclination of 10° relative to horizontal and is placed above half-partition B2 of the RPCs. PMT electronics are shielded thanks to lead blocks placed in order to protect them without stopping photons from going through the scintillators and the chamber.	5-11
388	5.11	Hit distributions over all 3 partitions of RE-4-2-BARC-161 chamber is showed on these plots. Top, middle and bottom figures respectively correspond to partitions A, B, and C. These plots show that some events still occur in other half-partitions than B2, which corresponds to strips 49 to 64, in front of which the trigger is placed, contributing to the inefficiency of detection of cosmic muons. In the case of partitions A and C, the very low amount of data can be interpreted as noise. On the other hand, it is clear that a little portion of muons reach the half-partition B1, corresponding to strips 33 to 48.	5-12
396	5.12	Results are derived from data taken on half-partition B2 only. On the 18 th of June 2014, data has been taken on chamber RE-2-BARC-161 at building 904 (Prevessin Site) with cosmic muons providing us a reference efficiency plateau of $(97.54 \pm 0.15)\%$ represented by a black curve. A similar measurement has been done at GIF on the 21 st of July with the same chamber giving a plateau of $(78.52 \pm 0.94)\%$ represented by a red curve.	5-13
402	5.13	Representation of the layout used for the simulations of the test setup. The RPC is represented as a yellow trapezoid while the two scintillators as blue cuboids looking at the sky. A green plane corresponds to the muon generation plane within the simulation. Figure 5.9a shows a global view of the simulated setup. Figure 5.9b shows a zommed view that allows to see the 2 scintillators as well as the full RPC plane.	5-14
407	5.14	γ flux $F(D)$ is plot using values from table 5.1. As expected, the plot shows similar attenuation behaviours with increasing distance for each absorption factors.	5-17
409	5.15	Figure 5.15a shows the linear approximation fit done via formulae 5.7 on data from table 5.2. Figure 5.15b shows a comparison of this model with the simulated flux using a and b given in figure 5.15a in formulae 5.4 and the reference value $D_0 = 50\text{cm}$ and the associated flux for each absorption factor F_0^{ABS} from table 5.1	5-19
413	5.16	Dose measurements has been done in a plane corresponding to the tents front side. This plan is 1900 mm away from the source. As explained in the first chapter, a lens-shaped lead filter provides a uniform photon flux in the vertical plan orthogonal to the beam direction. If the second line of measured fluxes is not taken into account because of lower values due to experimental equipments in the way between the source and the tent, the uniformity of the flux is well showed by the results.	5-21
419	5.17	5-22
420	5.18	Evolution of the maximum efficiency for RE2 (5.18a) and RE4 (5.18b) chambers with increasing extrapolated γ rate per unit area at working point. Both irradiated (blue) and non irradiated (red) chambers are shown.	5-24
423	5.19	Evolution of the working point for RE2 (5.19a) and RE4 (5.19b) with increasing extrapolated γ rate per unit area at working point. Both irradiated (blue) and non irradiated (red) chambers are shown.	5-24

426	5.20 Evolution of the maximum efficiency at HL-LHC conditions, i.e. a background hit rate per unit area of 300 Hz/cm ² , with increasing integrated charge for RE2 (5.20a) and RE4 (5.20b) detectors. Both irradiated (blue) and non irradiated (red) chambers are shown. The integrated charge for non irradiated detectors is recorded during test beam periods and stays small with respect to the charge accumulated in irradiated chambers.	5-25
432	5.21 Comparison of the efficiency sigmoid before (triangles) and after (circles) irradiation for RE2 (5.21a) and RE4 (5.21b) detectors. Both irradiated (blue) and non irradiated (red) chambers are shown.	5-25
435	5.22 Evolution of the Bakelite resistivity for RE2 (5.22a) and RE4 (5.22b) detectors. Both irradiated (blue) and non irradiated (red) chambers are shown.	5-26
437	5.23 Evolution of the noise rate per unit area for the irradiated chamber RE2-2-BARC-9 only.	5-26

442	A.2 Module V1190A <i>Trigger Matching Mode</i> timing diagram [64].	A-4
443	A.3 Structure of the ROOT output file generated by the DAQ. The 5 branches (<code>EventNumber</code> , <code>number_of_hits</code> , <code>Quality_flag</code> , <code>TDC_channel</code> and <code>TDC_TimeStamp</code>) are visible on the left panel of the ROOT browser. On the right panel is visible the histogram corresponding to the variable <code>nHits</code> . In this specific example, there were approximately 50k events recorded to measure the gamma irradiation rate on the detectors. Each event is stored as a single entry in the <code>TTree</code>	A-10
449	A.4 The effect of the quality flag is explained by presenting the content of <code>TBranch number_of_hits</code> of a data file without <code>Quality_flag</code> in Figure A.4a and the content of the same <code>TBranch</code> for data corresponding to a <code>Quality_flag</code> where all TDCs were labelled as <code>GOOD</code> in Figure A.4b taken with similar conditions. It can be noted that the number of entries in Figure A.4b is slightly lower then in Figure A.4a due to the excluded events.	A-12
455	A.5 Using the same data as previously showed in Figure A.4, the effect of the quality flag is explained by presenting the reconstructed hit multiplicity of a data file without <code>Quality_flag</code> in Figure A.5a and the reconstructed content of the same RPC partition for data corresponding to a <code>Quality_flag</code> where all TDCs were labelled as <code>GOOD</code> in Figure A.5b taken with similar conditions. The artificial high content of bin 0 is completely suppressed.	A-12
461	A.6 WebDCS DAQ scan page. On this page, shifters need to choose the type of scan (Rate, Efficiency or Noise Reference scan), the gamma source configuration at the moment of data taking, the beam configuration, and the trigger mode. These information will be stored in the DAQ ROOT output. Are also given the minimal measurement time and waiting time after ramping up of the detectors is over before starting the data acquisition. Then, the list of HV points to scan and the number of triggers for each run of the scan are given in the table underneath.	A-14

- 468 B.1 Example of expected hit time distributions in the cases of efficiency (Figure B.1a)
469 and noise/gamma rate per unit area (Figure B.1b) measurements as extracted from
470 the raw ROOT files. The unit along the x-axis corresponds to ns. The fact that
471 "the" muon peak is not well defined in Figure B.1a is due to the contribution of all
472 the RPCs being tested at the same time that don't necessarily have the same signal
473 arrival time. Each individual peak can have an offset with the ones of other detectors.
474 The inconsistancy in the first 100 ns of both time distributions is an artefact of the
475 TDCs and are systematically rejected during the analysis. B-16
476 B.2 The effect of the quality flag is explained by presenting the reconstructed hit multi-
477 plicity of a data file without `Quality_flag`. The artificial high content of bin 0 is the
478 effect of corrupted data. B-19
479 B.3 Display of the masking tool page on the webDCS. The window on the left allows the
480 shifter to edit `ChannelsMapping.csv`. To mask a channel, it only is needed to set the
481 3rd field corresponding to the strip to mask to 0. It is not necessary for older mapping
482 file formats to add a 1 for each strip that is not masked as the code is versatile and
483 the default behaviour is to consider missing mask fields as active strips. The effect
484 of the mask is directly visible for noisy channels as the corresponding bin turns red.
485 The global effect of masking strips will be an update of the rate value showed on the
486 histogram that will take into consideration the rejected channels. B-24

Investigating the TeV scale

672 „We may regard the present state of the universe as the effect of the
673 past and the cause of the future. An intellect which at any given mo-
674 ment knew all of the forces that animate nature and the mutual posi-
675 tions of the beings that compose it, if this intellect were vast enough
676 to submit the data to analysis, could condense into a single formula
677 the movement of the greatest bodies of the universe and that of the
678 lightest atom; for such an intellect nothing could be uncertain and
679 the future just like the past would be present before its eyes.”

680

681 - Pierre Simon de Laplace, *A Philosophical Essay on Probabilities*, 1814

Throughout history, physics experiment became more and more powerful in order to investigate finer details of nature and helped understanding the elementary blocks of matter and the fundamental interactions that bond them in the microscopic world. Nowadays, the Standard Model (SM) of particle physics is the most accurate theory designed to explain the behaviour of particles and was able to make very precise predictions that are constantly verified, although some hints of new physics are visible as bricks are still missing to have a global comprehension of the Universe.

To highlight the limits of the SM and test the different alternative theories, ever more powerful machines are needed. This is in this context that the Large Hadron Collider (LHC) has been thought and built to accelerate and collide particles at energies exceeding anything that had been done before. Higher collision energies and high pile-up imply the use of enormous detectors to measure the properties of the interaction products. The Compact Muon Solenoid (CMS) is a multipurpose experiment that have been designed to study the proton-proton collisions of the LHC and give answers on various high energy physics scenari. Nevertheless, the luminosity delivered by the collider will in the future be increased to levels beyond the original plans to improve its discovery potential giving no choice to experiments such as CMS to upgrade their technologies to cope with the increased radiation levels and detection rates.

2.1 The Standard Model of Particle Physics

In this early 21st century it is now widely accepted that matter is made of elementary blocks referred to as *elementary particles*. The physics theory that classifies and describes the best the behaviour and interaction of such elementary particles is the so called Standard Model that formalizes 3 of the 4 fundamental interactions (electromagnetic, weak and strong interactions). It's development took place during the 20th century thanks to a strong collaboration in between the theoretical and experimental physicists.

2.1.1 A history of particle physics

The idea that nature is composed of elementary bricks, called *atomism*, is not contemporary as it was already discussed by Indian or Greek philosophers during antiquity. In Greece, atomism has been rejected by Aristotelianism as the existance of *atoms* would imply the existance of a void that would violate the physical principles of Aristotle philosophy. Aristotelianism has been considered as a reference in the european area until the 15th century and the italian *Rinascimento* where antic text and history started to be more deeply studied. The re-discovery of Platon's philosophy would allow to open the door to alternative theories and give a new approach to natural sciences where experimentation would become central. A new era of knowledge was starting. By the begining of the 17th century, atomism was re-discovered by philosophers and the very first attempt to estimate an *atom* size would be provided by Magnetus in 1646. Although his *atoms* correspond to what would nowadays be called *molecules*, Magnetus achieved feats by calculating that the number of molecules in a grain of incense would be of the order of 10^{18} simply by considering the time necessary to smell it everywhere in a large church after the stick was lit on. It is now known that this number only falls short by 1 order of magnitude.

An alternative philosophy to atomism popularized by Descartes was corpuscularianism. Built on ever divisible corpuscles, contrary to atoms, it's principles would be mainly used by alchemists like Newton who would later develop a corpuscular theory of light. Boyle would combine together ideas of both atomism or corpuscularianism leading to mechanical philosophy. The 18th century have

seen the development of engineering providing philosophical thought experiments with repeatable demonstration and a new point of view to explain the composition of matter and Lavoisier would greatly contribute to chemistry and atomism by publishing in 1789 a list of 33 chemical elements corresponding to what is now called *atoms*. In the early 19th century Dalton would summarize the knowledge on composition of matter and Fraunhofer would invent the spectrometer and discover the spectral lines. The rise of atomic physics, chemistry and mathematical formalism would unravel the different atomic elements and ultimately, the 20th century would see the very first sub-atomic particles.

Discovery of the inner structure of the atom

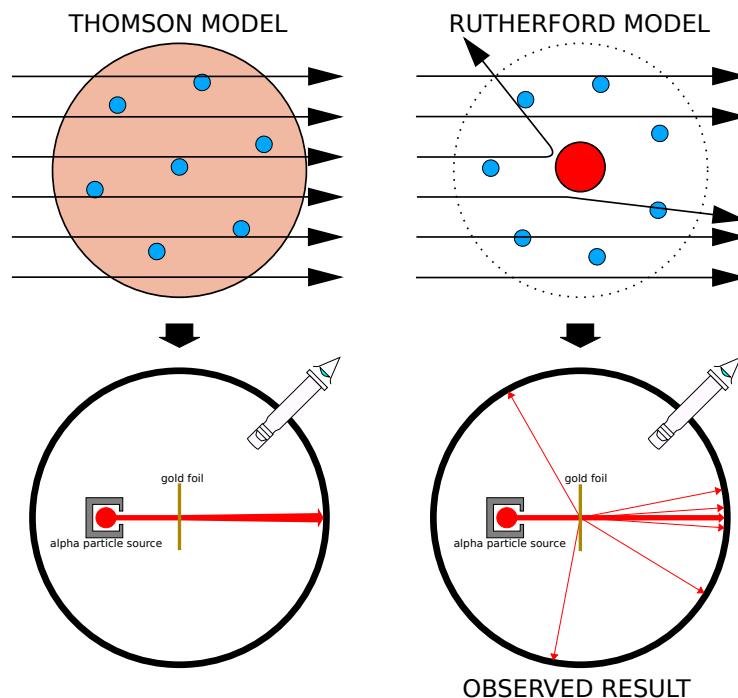

Figure 2.1: Through the gold foil experiment Rutherford could show that most of the mass of atoms was contained in a positively charged nucleus and could then propose a more accurate atomic model than that of Thomson.

The negative *electron* would be the first to be discovered in 1897 by Thomson after 3 decades of research on cathode rays by proving that the electrification observed in an electroscope, as reported by Perrin, was due to the rays themselves and that they had to be composed of electrically charged particles. In 1900, Becquerel would show the *beta rays* emitted by radium had the same charge over mass ratio than what measured by Thomson for cathode rays, pointing to electrons as a constituent of atoms. In 1907, Rutherford and Royds showed that *alpha* particles, once captured in a tube and subjected to an electric spark causing an electron avalanche, where helium ions as they could combine with 2 electrons to form a ${}^4\text{He}$. This discovery was directly followed by the constraint of the atom structure in 1909 through the gold foil experiment in which the deflection angle of alpha particles fired at a very thin gold foil was measured and highlighted atoms where mainly empty with

743 nearly all its mass contained into a tiny positively charged *nucleus*. With these two observations,
 744 he could formulate the Rutherford model of the atom in 1911, shown together with the Thomson
 745 plum pudding model in Figure 2.1. The link in between atomic number and number of positive and
 746 negative charges contained into the atoms would fast be understood and the different kind of element
 747 transmutation appeared to be purely nuclear processes making clear that the electromagnetic nature
 748 of chemical transformation could not possibly change nuclei. Thus a new branch in physics appeared
 749 to study nuclei exclusively: the nuclear physics.

750 Moreover, in 1913 quantum physics would be introduced into the atomic model by Bohr based
 751 on the assumptions of Plank to explain spectral lines, and other observed quantum effects. The same
 752 year, Moseley would confirm Bohr's model and Debye would extend it by introducing elliptical
 753 orbits.

754 By studying alpha emission and the product of their interaction with nitrogen gas, Rutherford
 755 reported in 1919 the very first nuclear reaction leading to the discovery that the hydrogen nucleus was
 756 composed of a single positively charged particle that was later baptised *proton*. This idea came from
 757 1815 Prout's hypothesis proposing that all atoms are composed of "*protyles*" (i.e. hydrogen atoms).
 758 By using scintillation detectors, Rutherford could highlight typical hydrogen nuclei signature and
 759 understand that the impact of alpha particles with nitrogen would knock out an hydrogen nucleus
 760 and produce an oxygen 17, as explicated in Formula 2.1 and would then postulate that protons are
 761 building bricks of all elements.

762 With this assumption and the discovery of isotopes together with Aston, elements with identical
 763 atomic number but different masses, Rutherford would propose that all elements' nuclei but hydrogen's are composed of both charged particles, protons, and of chargeless particles, which he called
 764 *neutrons*, and that these neutral particles would help maintaining nuclei as one, as charged protons
 765 were likely to electrostatically repulse each other, and introduced the idea of a new force, a *nuclear*
 766 force. Though the first idea concerning neutrons was a bond state of protons and electrons as it was
 767 known that the beta decay, emitting electrons, was taking place in the nucleus, it was then showed
 768 that such a model would hardly be possible due to Heisenberg's uncertainty principle and by the
 769 recently measured *spin* of both protons and electrons. The spin, discovered through the study of
 770 the emission spectrum of alkali metals, would be understood as a "two-valued quantum degree of
 771 freedom" and formalized by Pauli and extended by Dirac, to take the relativist case into account.
 772 Measured to be $\frac{1}{2}\hbar$ for both, it was impossible to arrange an odd number of half integer spins and
 773 obtain a global nucleus spin that would be integer. Finally, in 1932, following the discovery of a new
 774 neutral radiation, Chadwick could discover the neutron as an uncharged particle with a mass similar
 775 to that of the proton whose half integer spin would reveal to be the solution to explain the nuclear
 776 spin.

778 Development of the Quantum Electrodynamics

779 Historically, the development of the quantum theory revolved around the question of emission and
 780 absorption of discrete amount of energy through light. Einstein used the initial intuition of Plank
 781 about the black-body radiation to develop in 1905 a model to explain the photoelectric effect in
 782 which light was described by discrete quanta now called *photons*. For this model, Einstein introduced
 783 the concept of wave-particle duality as classical theory was not able to describe the phenomenon.
 784 With the new understanding of atoms and of their structure, classical theories also proved unable

785 to explain atoms stability. Indeed, using classical mechanics, electrons orbiting around a nucleus
 786 should radiate an energy proportional to their angular momentum and thus lose energy through
 787 time and the spectrum of energy emission should then be continuous, but it was known since the
 788 19th century and the discovery of spectral lines that the emission spectrum of material was discrete.

789 This was Bohr who first suggested that a quantum description of the atom was necessary in 1913.
 790 Using the correspondence principle stating that at large enough numbers the quantum calculations
 791 should give the same results than the classical theory, he proposed the very first quantum model
 792 of the hydrogen atom explaining the line spectrum by introducing the principal quantum number
 793 n describing the electron shell. This model would then be improved by Sommerfeld that would
 794 quantize the z-component of the angular momentum, leading to the second and third quantum
 795 numbers, or azimuthal and magnetic quantum number, l and m defining for the second the orbital
 796 angular momentum of the electrons on their shells and thus, the shape of the orbital, and for the third
 797 the available orbital on the subshell for each electron. Nevertheless, although the model was not only
 798 limited to spherical orbitals anymore, making the atom more realistic, the Zeeman effect couldn't be
 799 completely explained by just using n , l and m . A solution would be brought after the discovery of
 800 Pauli in 1924, as Uhlenbeck, Goudsmit, and Kramers proposed in 1925 the idea of intrinsic rotation
 801 of the electron, introducing a new angular momentum vector associated to the particle itself, and
 802 not to the orbital, and associated to a new quantic number s , the *spin* projection quantum number
 803 explaining the lift of degeneracy to an even number of energy levels.

804 The introduction of the *spin* happened 1 year after another attempt of improvement of the theory
 805 was made by De Broglie in his PhD thesis. The original formulation of the quantum theory only
 806 considered photons as energy quanta behaving as both waves and particles. De Broglie proposed
 807 that all matter are described by waves and that their momentum is proportional to the oscillation of
 808 quantized electromagnetic field oscillators. This interpretation was able to reproduce the previous
 809 version of the quantum energy levels by showing that the quantum condition involves an integer
 810 multiple of 2π , as shown by Formula 2.2.

$$p = \hbar k \Leftrightarrow \int pdx = \hbar \int kdx = 2\pi\hbar n \quad (2.2)$$

811 Although the intuition of De Broglie about the wave-particle duality of all matter, his interpretation
 812 was semiclassical and it's in 1926 that the first fully quantum mechanical wave-equation would
 813 be introduced by Schrödinger to describe electron-like particles, reproducing the previous semiclassical
 814 formulation without inconsistencies. This complexe equation describes the evolution of the
 815 wave function Ψ of the quantum system, defined by its position vector \mathbf{r} and time t as an energy
 816 conservation law, in which the hamiltonian of the system \hat{H} is explicit, by solving the Equation 2.3.

$$i\hbar \frac{\partial}{\partial t} |\Psi(\mathbf{r}, t)\rangle = \hat{H} |\Psi(\mathbf{r}, t)\rangle \quad (2.3)$$

817 In 1927, Dirac would go further in his paper about emission and absorption of radiation by
 818 proposing a second quantization not only of the physical process at play but also of the electromagnetic
 819 field, providing the ingredients to the first formulation of *Quantum Electrodynamics (QED)*
 820 and the description of photon emission by electrons dropping into a lower energy state in which the
 821 final number of particles is different than the initial one. To complete this model to the many-body
 822 wave functions of identical particles, Jordan included creation and annihilation operators for fields
 823 obeying Fermi-Dirac statistics leading to a model describing particles that would be referred to as
 824 *fermions*. Nevertheless, in order to properly treat electromagnetism, the incorporation of the relativ-

825 ity theory developed by Einstein. Including gravity into quantum physics still is a challenge nowa-
 826 days, but in 1928 Pauli and Jordan would show that special relativity's coordinate transformations
 827 could be applied to quantum fields as the field commutators were Lorentz invariant. Finally derived
 828 the same year, the Dirac equation, shown as Equation 2.4, similarly to Schrödinger's equation, is a
 829 single-particle equation but it incorporates special relativity in addition to quantum mechanics rules.
 830 It features the 4×4 gamma matrices γ^μ built using 2×2 Pauli matrices and unitary matrix, the
 831 4-gradient ∂_μ , the rest mass m of any half integer spin massive particle described by the wave func-
 832 tion $\psi(x, t)$, also called a Dirac spinor, and the speed of light c . In addition to perfectly reproduce
 833 the results obtained with quantum mechanics so far, it also provided with *negative-energy solutions*
 834 that would later be interpreted as a new form of matter, *antimatter* and give a theoretical justifica-
 835 tion to the Pauli equation that was phenomenologically constructed to account for the spin as in the
 836 non-relativistic limit, the Dirac equation is similar.

$$i\hbar\gamma^\mu\partial_\mu\psi - mc\psi = 0 \quad (2.4)$$

837 The successes of the QED was soon followed with theoretical problems as computations of any
 838 physical process involving photons and charged particles were showed to be only reliable at the first
 839 order of perturbation theory. At higher order of the theory, divergent contributions were appearing
 840 giving nonsensical results. Only two effects were contributing to these infinities.

- 841 • The self-energy of the electron (or positron), the energy that the particle has due its own
 842 interaction with its environment.
- 843 • The vacuum polarization, virtual electron–positron pairs produced by a background electro-
 844 magnetic field in the vacuum which is not an "empty" space. These virtual pairs affect the
 845 charge and current distributions generated by the original electromagnetic field.

846 Solving this apparent problem was done by carefully defining the concepts of each observables,
 847 for example mass or charge, as these quantities are understood within the context of a non-interacting
 848 field equation, and that from the experiment point of view, they are abstractions as what is measured
 849 are "renormalized observables" shifted from there "bare" value by the interaction taking place in
 850 the measuring process. The infinities needed to be connected to corrections of mass and charge
 851 as those are fixed to finite values by experiment. This was the intuition of Bethe in 1947 who
 852 successfully computed the effect of such *renormalization* in the non-relativist case. Fully covariant
 853 formulations of QED including renormalization was achieved by 1949 by Tomonaga, Schwinger,
 854 Feynman and Dyson and Feynman is now famous for his association of diagrams to the term of
 855 the scattering matrix, greatly simplifying the representation and computation of interactions as the
 856 diagrams directly corresponded the measurable physical processes and would then be used in every
 857 quantum field theories. With the resolution of infinities, QED had mostly reached its final form,
 858 being still today the most accurate physical theory and would serve as a model to build all other
 859 quantum field theories.

860 Development of the quark model and Quantum Chromodynamics

861 To explain the nuclear force that holds *nucleons* (protons and neutrons) together, Yukawa theoreti-
 862 cally proposed in 1934 the existence of a force carrier called *meson* due to it's predicted mass in
 863 the range in between the electron and nucleon masses. Discovered in 1936 by Anderson and Ned-
 864 dermeyer, and confirmed using bubble chambers in 1937 by Street and Stevenson, a first meson

candidate was observed in the decay products of cosmic rays. Assuming it had the same electric charge than electrons and protons, this particle was observed to have a curvature due to magnetic field that was sharper than protons but smoother than electrons resulting in a mass in between that of electrons and protons. But its properties were not compatible with Yukawa's theory, which was emphasized by the discovery of a new candidate in 1947, again in cosmic ray products using photographic emulsions.

This new candidate, although it had a similar mass than the already believed *meson*, would rather decay into it. For distinction, the first candidate would then be renamed "*mu meson*" when the second would be the "*pi meson*". The *mu meson* was behaving like a heavy electron and didn't participate in the strong interaction whereas the pion was believed to be the carrier of the nuclear interaction. This lead to classify the *mu* in a new category of particles called *leptons* together with the electron that shared similar properties and *the neutrino*, and be renamed *muon*. The *pi meson* was finally found to be a triplet of particles: a positively charged, a negatively charged, and a neutral particle. The neutral *pi meson* has been more difficult to identify as it wouldn't leave tracks on emulsions nor on bubble chambers and needed to be studied via it's decay products. It was ultimately identified in University of California's cyclotron in 1950 through the observation of its decay into 2 photons.

Also discovered in 1947 but in cloud chamber photographs, the *K meson* as also been an important step towards the establishment of the Standard Model. A triplet of particle, 2 charged and a neutral, with a mass roughly half that of a proton, were reported. These particles were baptised *K meson* in contrast to the "light" *pi* and *mu* "L-mesons". The particularity of the *K* were there very slow decays with a typical lifetime of the order of 10^{-10} s much greater than the 10^{-23} s of *pi*-proton reactions. The concept of *strangeness*, a new quantum number was then introduced by Pais as an attempt to explain this phenomenon as *strange* particles appeared as a pair production of a strange and anti-strange particle.

With the development of synchrotrons, the particle *zoo* would grow to several dozens during the 1950s as higher energies were reachable through acceleration. In 1961, a first classification system, called Eightfold Way, was proposed by Gell-Mann and finding its roots in the Gell-Mann–Nishijima formula, which relates the electric charge Q , the third component of the isospin I_3 , the *baryon* number B and the strangeness S , as explicitated in Formula 2.5. The isospin was a quantum number introduced in 1932 to explain symmetries of the newly discovered neutron using representation theory of SU(2). The baryon number, was introduced by Nishijima as a quantum number for baryons, i.e. particles of the same family as nucleons. The mesons were classified in an octet and baryons of spin $\pm \frac{1}{2}$ and $\pm \frac{3}{2}$ were respectively classified into an octet and a decuplet, as shown in Figure 2.2. To complete the baryon decuplet, Gell-Mann predicted the existance of baryon Ω^- which would later be discovered in 1964.

$$Q = I_3 + \frac{1}{2}(B + S) \quad (2.5)$$

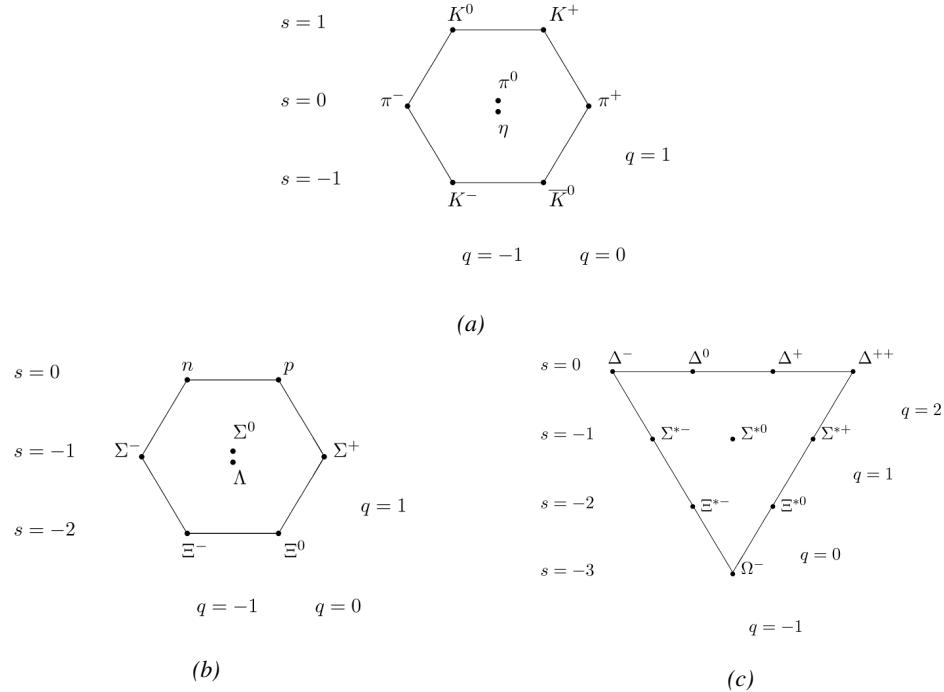

Figure 2.2: Figure 2.2a: Meson octet. Figure 2.2b: Baryon octet. Figure 2.2c: Baryon decuplet.

Strong of this classification using an SU(3) flavor symmetry, Gell-Mann, and independently Zweig, would propose a full theoretical model in which *hadrons* (strongly interacting particles, i.e. mesons and baryons) were not elementary particles anymore. They would rather be composed with 3 flavors of particles called *quarks* and there anti-particles. The 3 flavors were called *up*, *down* and *strange*. *Up* and *down* would be used to explain the nucleons and non-strange mesons, while *strange* would come into the composition of hadrons showing strangeness. *Up* and *down* flavors would be discovered in 1968 thanks to the deep inelastic scattering experiments conducted at the Stanford Linear Accelerator Center (SLAC), and *strange* could only be indirectly validated even though it provided a robust explanation to *kaon* (K) and *pion* (π). However, in the decade following the Gell-Mann-Zweig quark model proposition, several improvement to the model were brought, first by Glashow and Bjorken the same year that predicted the existence of a fourth quark flavor, the *charm*, that would equalize the then known number of quarks and leptons and finally in 1973 by Kobayashi and Maskawa that would increase the number of quarks to 6 to explain the experimental observation of CP violation. These two quarks would be referred to as *top* and *bottom* for the first time in 1975. It's only after these additions to the quark model that finally the *charm* would be discovered in 1974 at both SLAC and Brookhaven National Laboratory (BNL). A meson where the *charm* was bound with an *anti-charm*, called J/ψ , would help convince the physics community of the validity of the model. The *top* would be discovered soon after in 1977 in Fermilab and indicate the existence of the *bottom* that would resist to discovery until Fermilab's experiments CDF and D \emptyset in 1995 due to its very large mass and the energy needed to produce it.

As remarked by Struminsky, the original quark model proposal composed of 3 quarks should possess an additional quantum number due to mesons such as Ω^- or Δ^{++} . Indeed, these mesons are composed of 3 identical quarks, respectively 3 *strange* and *up* quark, with parallel spins, which

should be forbidden by the exclusion principle. Independentle, Greenberg and Han-Nambu proposed an additional SU(3) degree of freedom possessed by the quarks, that would later be refered to as *color charge gauge*, that could interact through *gluons*, the gauge boson octet corresponding to this degree of freedom. Nevertheless, as observing free quarks proved to be impossible, two visions of the quarks were argued mainly due to the failures to observe these particles free to prove their existence. On one side, Gell-Mann proposed to see quarks as mathematical construct instead of real particles, as they are always confined, implying that quantum field theory would not describe entirely the strong interaction. Opposed to this vision, Feynman on the contrary argued that quarks were real particles, that he would call *partons*, that should be described as all other particles by a distribution of position and momentum. The implications of quarks as point-like particles would be verified at SLAC and the concept of *color* would be added to the quark model in 1973 by Fritzsch and Leutwyler together with Gell-Mann to propose a description of the strong interaction through the theory of Quantum Chromodynamics (QCD). The discovery the same year of asymptotic freedom within the QCD by Groos, Politzer and Wilczek, allowed for very precise predictions thanks to the perturbation theory. Nowadays, the confinement of quarks is studied in experiments such as ALICE, through exploration of the quark-gluon plasma.

939 The Weak interaction, spontaneous symmetry breaking, the Higgs mechanism and the Elec- 940 troweak unification

941 The weak interaction is the process that causes radioactive decays. Thanks to the neutron discovery,
942 Fermi could explain in 1934 the beta radiations through the beta decay process in which the neutron
943 decays into a proton by emitting an electron. Though the missing energy observed during this
944 process triggered a huge debate about the apparent non conservation of energy, momentum and spin
945 of the process, Fermi, as Pauli before him, proposed that the missing energy was due to a neutral
946 not yet discovered particle that would then be baptised *neutrino*. The impossibility to detect such
947 a particle would leave some members of the scientific community sceptical, but hints of energy
948 conservation and of the existence of the neutrino were provided by measuring the energy spectrum
949 of electrons emitted through beta decay, as there was a strict limit on their energy. It's only 30 years
950 later in 1953 that it would be discovered by the team of Cowan and Reines using the principle of
951 inverse beta decay described through Formula 2.6. The experiment consisted in placing water tanks
952 sandwiched in between liquid scintillators near a nuclear reactor with an estimated neutrino flux of
953 $5 \times 10^{13} \text{ s}^{-1} \text{ cm}^{-2}$. However, in order to explain the absence of some reactions in the experiment
954 of Cowan and Reines, and constraint the beta decay theory of Fermi and extend it to the case of
955 the muon, Konopinski and Mahmoud proposed in 1953 that the muon decay would eject a particle
956 similar to the neutrino and thus predicted the existence of a muon neutrino that would be different
957 than the one involved in the beta decay, related to the electron. With this, the idea of lepton number
958 would arise. The muon neutrino would successfully be detected in 1962 by Lederman, Schwartz and
959 Steinberger.

$$\bar{\nu} + p \rightarrow n + e^+ \quad (2.6)$$

960 The theory could not be valid though as the probability of interaction, called cross-section, would
961 have been increasing without bond with the square of the energy. Fermi assumed in a two vector
962 current coupling but Lee and Yang noted that an axial current could appear and would violate parity.
963 The experiment of Wu in 1956 would confirm the parity violation and Gamow and Teller would try to
964 account for it by describing Fermi's interaction through allowed (parity-violating) and superallowed

965 (parity-conserving) decays. But the success of QED as a quantum field theory would spark the
966 development of such a theory to describe the weak interaction.

967 As previously discussed, the great success of QED was built on an underlying symmetry, inter-
968 preted as a gauge invariance so that the effect of the force is the same in all space-time coordinates,
969 and of the possibility to renormalize it in order to absorb the infinities. Independently in 1958,
970 Glashow, and Salam and Ward used 1957 Schwinger ideas about vector intermediary for the decay
971 processes, could find a way to unite both the electromagnetic and weak interaction into a gauge
972 theory involving 4 gauge bosons, 3 of which were massive and carried out the weak interaction and
973 a massless boson carrying the electromagnetic interaction. Among the 3 massive bosons, 2 were
974 charged and 1 was neutral, similarly to the previously theorized *pi meson* vector of the Yukawa
975 model and all have a mass much greater than nucleons and thus a very short life time implying a
976 finite very short range contrary to the contact interaction originally proposed by Fermi.

977 Breakthrough in other fields of physics contributed in giving theoretical support and interpreta-
978 tion to the unified electroweak theory. The stepping stone would be the use of spontaneous symmetry
979 breaking that was inspired to Nambu at the end of the 1950s following the development of the BCS
980 superconductivity mechanism in 1957. Cooper had shown that BCS pairs, pairs of electrons bound
981 together at low temperature, could have lower energy than the Fermi energy and where responsi-
982 ble for superconductivity. This lead to the discovery of Goldstone-Nambu bosons as a result of the
983 spontaneous breaking of the chiral symmetry in a theory describing nucleons and mesons devel-
984 opped by Nambu and Jona-Lasinio in 1961, and now understood as a low-energy approximation of
985 QCD. Similarly to mechanism of energy gap appearance in superconductivity, the nucleon mass
986 is suggested to the result of a self-energy of a fermion field and is studied through a four-fermion
987 interaction in which, as a consequence of the symmetry, bound states of nucleon-antinucleon pairs
988 appear and can be regarded as virtual pions. Though the symmetry is maintained in the equations,
989 the ground state is not preserved. Goldstone would later the same year show that the bound states
990 corresponds to spinless bosons with zero mass.

991 Although the model in itself didn't revolutionize particle physics, spontaneous symmetry break-
992 ing would be generalized to quantum field theories. As all fundamental interactions are described
993 using gauge theories based on underlying symmetries, processes such as the chiral symmetry break-
994 ing would be introduced soon after the publication of Nambu and Jona-Lasinio. In 1962, Anderson,
995 following an idea of Schwinger who suggested that zero-mass vector bosons were not necessarily
996 required to describe the conservation of baryons contrary to the bosons emerging from chiral sym-
997 metry breaking, discussed the implications of spontaneous symmetry breaking in particles physics.
998 A model was finally independently built in 1964 by Brout and Englert, Higgs, and Guralnik, Hagen,
999 and Kibble, who discovered that combining an additional field into a gauge theory in order to break
1000 the symmetry, the resulting gauge bosons acquire a nonzero mass. Moreover, Higgs stated that this
1001 implied the existence of at least one new massive, i.e. self-interacting, scalar boson, that are now
1002 known as *Higgs bosons* corresponding to this additional field. The Higgs mechanism today specifi-
1003 cally refers to the process through which the gauge bosons of the weak interaction acquire mass. In
1004 1968, Weinberg could point to the Higgs mechanism to integrate a Higgs field into a new version
1005 of the electroweak theory in which the spontaneous symmetry breaking mechanism of the Higgs
1006 field would explicitly explain the masses of the weak interaction gauge bosons and the zero-mass
1007 of photons.

1008 2.1.2 Construction and test of the model

1009 The Standard Model of particle physics was built in the middle of the 1970s after the experimental
 1010 confirmation of the existence of quarks. It is based on the assembly of the models previously intro-
 1011 duced and describing the fundamental interactions, except for gravitation, and their gauge bosons
 1012 as well as the way elementary "matter" particles interact with the fields associated with these force
 1013 carriers. In this sense, the development of QED and the unification of the electroweak interaction,
 1014 of the Yukawa interaction and of QCD, and of the Higgs mechanism made it possible to explain most
 1015 of contemporary physics.

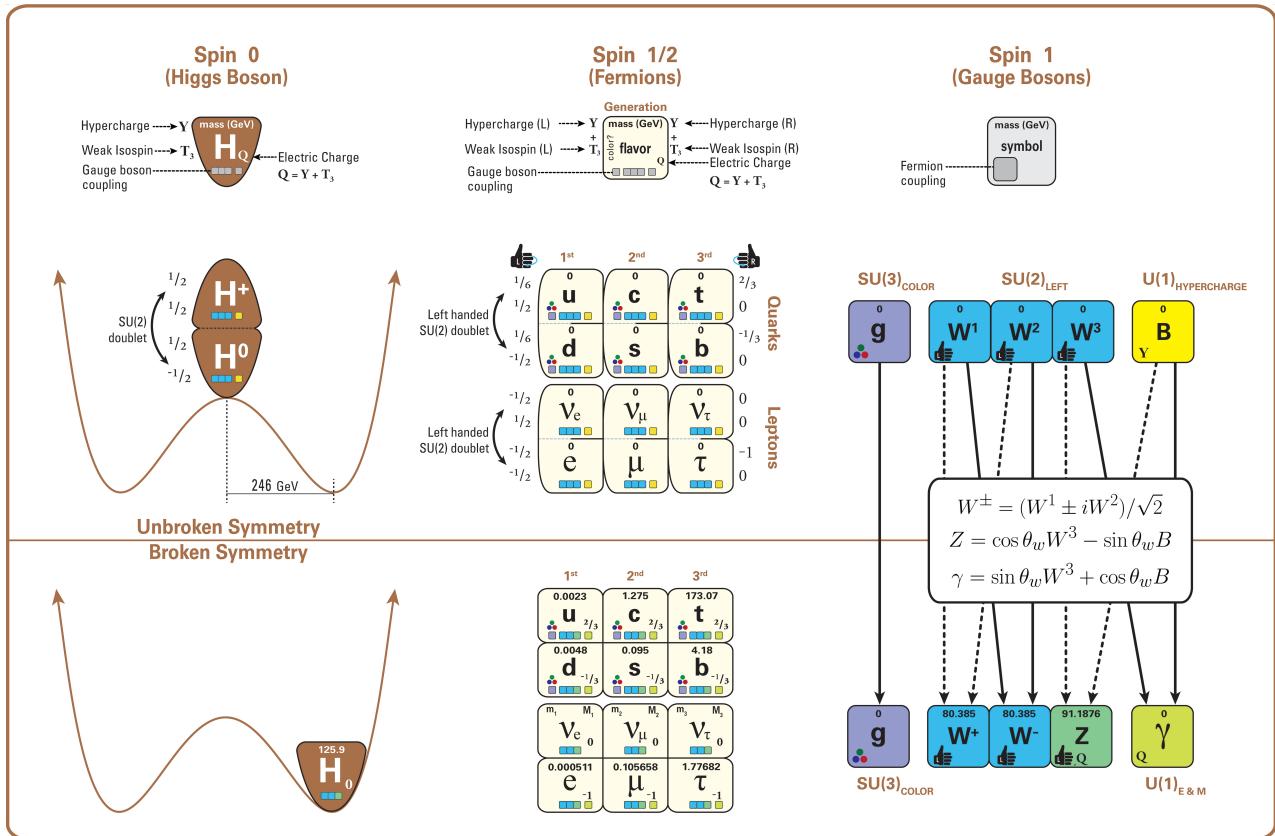

Figure 2.3: The elementary particles of the Standard Model are showed along with their names and properties. Their interactions with the strong, weak and electromagnetic forces have been explicited using color squares. In the left column, the scalar higgs boson is depicted, while the central is focused on the matter particles, the fermions, and the right on the force carriers, the gauge bosons. The role of the Higgs boson in electroweak symmetry breaking is highlighted, and the corresponding way properties of the various particles differ in the (high-energy) symmetric phase (top) and the (low-energy) broken-symmetry phase (bottom) are showed.

1016 In the SM, "matter" particles, are described by 12 fermion fields of spin $\frac{1}{2}$ obeying the Fermi-
 1017 Dirac statistics, i.e. subjected to the Pauli exclusion principle. To each fermion is associated its
 1018 corresponding antiparticle. The fermions are classified according to the way they interact and, thus,
 1019 according to the charges they carry. 6 of them are classified as quarks (u, d, c, s, t , and b) and
 1020 are subjected to all interactions and the 6 others as leptons ($e^-, \mu^-, \tau^-, \nu_e, \nu_\mu$, and ν_τ). Leptons

1021 are not subjected to the strong interaction and among them, the 3 neutrinos only interact weakly as
 1022 they are neutral particles, which explains why they are so difficult to detect. The gauge boson fields
 1023 are the gluons g for the strong interaction, the photon γ for the electromagnetic interaction and the
 1024 weak bosons W^+ , W^- , and Z^0 for the weak interaction. Finally, the Higgs field H^0 is responsible,
 1025 through the spontaneous symmetry breaking, of the mixing of the massless electroweak boson fields
 1026 W_1 , W_2 , W_3 , and B leading to the observable states γ , W^+ , W^- , and Z^0 that can gain mass while
 1027 interacting with the Higgs field. This picture of the SM is summarized through Figure 2.3 where the
 1028 antifermions are not showed.

1029 When the model was first finalized, the existence of the weak gauge bosons, of the charm, of the
 1030 third quark generation composed of top and bottom quarks to explain the observed CP violation was
 1031 not proven but the predictions were measured with good precision in the years following. First, the
 1032 charm quark would be discovered in 1974, followed by the bottom quark in 1977. The weak bosons
 1033 would be discovered during the next decade in 1983. The top quark would resist until 1995 due to
 1034 its very large mass but would offer the last piece of the elementary QCD particles. The very last
 1035 predicted elementary particle of the model that was not observed yet would prove to be very difficult
 1036 to observe. the Higgs boson needed the start of the LHC to finally be observed in 2012. A few years
 1037 more of tests were necessary to measure its properties to confirm the observation of a scalar boson
 1038 compatible with the predicted Higgs boson H^0 . Eventhough only quark-antiquark (mesons) and 3
 1039 quark states (baryons) were observed, exotic hadrons were not forbidden by QCD and no limit of
 1040 quark is imposed by the theory. Moreover, gluons could form bond states by themselves and with
 1041 quarks. These two types of states are called *glueballs* and *hybrid hadrons*. For decades, experi-
 1042 ments have been conducted without confirmation of such possible states existing. Nevertheless, in
 1043 2014, tetraquarks were observed by LHCb, one of LHC's main experiments, and in 2015, the same
 1044 experiment reported the discovery of pentaquarks making the SM one of the best tested theories of
 1045 physics.

1046 2.1.3 Investigating the TeV scale

1047 Even though the SM is a well tested theory, several hints of physics going beyond its scope have
 1048 been observed. First of all, gravity is not explained through this model and huge difficulties are en-
 1049 countered when trying to include gravitation. The strength of gravitational interaction is expected to
 1050 be negligible at the scale of elementary particles, nevertheless, adding gravitation in the perspective
 1051 of developing a "theory of everything" leads to divergent integrals that could not be fixed through
 1052 renormalization.

1053 Moreover, the SM considers neutrinos to be massless but it was shown in the late 1960s by the
 1054 Homestake experiment that the flux of solar neutrinos (i.e. ν_e) measured didn't match the predicted
 1055 values due to neutrino oscillations, confirmed in the early 2000s by the Sudbury Neutrino Obser-
 1056 vatory. This oscillation implies that neutrinos that can be observed are a superposition of massive
 1057 neutrino states. The research on neutrino oscillation is already quite advanced with experiments
 1058 looking at atmospheric, reactor or beam neutrinos in order to determine the elements of the mixing
 1059 matrix similar to the CKM matrix describing the mixing of quarks. Nevertheless, no answer to the
 1060 origin of neutrino mass is provided.

1061 Another intriguing fact is that the universe is dominated by matter. However, the SM predicted
 1062 that matter and antimatter should have been created in equal amounts and no mechanism is able to
 1063 explain this matter-antimatter asymmetry. Although this asymmetry is seen from the visible uni-
 1064 verse, it may be possible that other unknown regions of the Universe are dominated by antimatter.

1065 Another possibility to explain the apparent asymmetry would be the existence of a electric dipole
1066 in any fundamental particle that would permit matter and antimatter particles to decay at different
1067 rates.

1068 The discrepancy of velocity dispersion of stars in galaxies with respect to the visible mass they
1069 contain is known since the end of the 19th century where Kelvin proposed that this problem could
1070 be solved if a "*great majority of [the stars] would be dark bodies*". Throughout the 20th century,
1071 physicists like Kapteyn, Zwicky, showed the first hints of a "*dark matter*" by studying star veloc-
1072 ities and galactic clusters, followed by robust measurements of galaxy rotation curves by Babcock
1073 which suggested that the mass-to-luminosity ratio was different from what would be expected from
1074 watching the visible light. Later in the 1970s, Rubin and Ford from direct light observations and
1075 Rogstad and Shostak from radio measurements showed that the radial velocity of visible objects in
1076 galaxies was increasing with increasing distance to the center of the galaxy. Finally observation of
1077 lensing effect by galaxy clusters, temperature distribution of hot gas in galaxies and clusters, and
1078 the anisotropies in the Cosmic Microwave Background (CMB) kept on pointing to a "*dark matter*".
1079 From all the data accumulated, the visible matter would only account to no more than 5% of the total
1080 content on the visible universe. Alternative theories have tried to investigate modified versions of
1081 the General Relativity as this theory is only well tested at the scale of the solar system but is not suf-
1082 ficiently tested on wider ranges or even theories in which gravitation is not a fundamental force but
1083 rather an emergent one, but so far, such theories have difficulties to reproduce all the experimental
1084 observations as easily as through dark matter.

1085 A possible theory to offer dark matter candidates would be supersymmetry (SUSY) which pro-
1086 poses a relationship in between bosons and fermions. In this model, each elementary particle,
1087 through a spontaneous spacetime symmetry breaking mechanism would have a *super partner* from
1088 the other family of particles. On top of providing heavy dark matter candidates, supersymmetry
1089 could also help solving the *Hierarchy problem*, the very large scale difference in between the weak
1090 interaction and gravity, although, as mentioned before, in the case gravity is found not to be a funda-
1091 mental force, this problem would automatically fade.

1092
1093 All these different aspects of physics beyond the Standard Model of particle physics and the
1094 Standard model itself can be tested through the use of very energetic and intense hadron and ion col-
1095 liders. The LHC at CERN is a perfect tool to seek answers to these open questions except maybe for
1096 the gravity as gravity is extremely weak at particles level. For example, one of LHCb experiment's
1097 goal is to investigate CP-violation and thus baryonic asymmetry. In 2017, the collaboration has an-
1098 nounced to have so far a 3.3σ statistical significance over a CP-violation through the study of the
1099 decays of Λ_b^0 and $\overline{\Lambda}_b^0$ into a proton (or antiproton) and 3 pions. Many analysis teams are also working
1100 hard on supersymmetry both in ATLAS and CMS collaborations, the two multipurpose experiments
1101 of LHC, even though no evidence of a supersymmetrical theory was seen, the few hint having the
1102 tendency to confirm the standard model. These experiments also have the possibility to investigate
1103 ways to explain Majorana neutrino mass through Yukawa interactions of scalar particles.

1104 The higher the center-of-mass energy, the smaller details the experiments will be able to see, the
1105 heavier the potential particle creation barrier will be, the stronger the cross-section of certain rare
1106 decay channels will be. As a comparison, with collisions happening at 14 TeV, the LHC is approxi-
1107 mately 2 orders of magnitude more sensitive to the Higgs than the Tevatron was with its already very
1108 powerful 2 TeV. All these advantages eventually lead to new discoveries and deeper understanding
1109 of the models describing our Universe. But the LHC only is a step forward to gather more precise
1110 tests of the Standard Model and new knowledge about the physics beyond it. A successful physics

1111 campaign will probably serve to justify the building of new accelerators with even greater discovery
1112 potential like for example the Future Circular Collider (FCC) that would push even further the study
1113 of the unanswered questions of contemporary physics.

1114 2.2 The Large Hadron Collider & the Compact Muon Solenoid

1115 Throughout its history, CERN has played a leading role in high energy particle physics. Large re-
1116 gional facilities such as CERN were thought after the second world war in an attempt to increase
1117 international scientific collaboration and allows scientists to share the forever increasing costs of
1118 experiment facilities required due to the need for increasing the energy in the center of mass to
1119 deeper probe matter. The construction of the first accelerators at the end of the 50s, the Synchro-
1120 cyclotron (SC) and the Proton Synchrotron (PS), was directly followed by the first observation of
1121 antinuclei in 1965 [1]. Strong from the experience of the Intersecting Storage Rings (ISR), the very
1122 first proton-proton collider that showed hints that protons are not elementary particles, the Super
1123 Proton Synchrotron (SPS) was built in the 70s to investigate the structure of protons, the preference
1124 for matter over antimatter, the state of matter in the early universe or exotic particles, and lead to
1125 the discovery in 1983 of the W and Z bosons [2–5]. These newly discovered particles and the elec-
1126 troweak interaction would then be studied in details by the Large Electron-Positron (LEP) collider
1127 that will help to prove in 1989 that there only are three generations of elementary particles [6]. The
1128 LEP would then be dismantled in 2000 to allow for the LHC to be constructed in the existing tunnel.

1129 2.2.1 LHC, the most powerful particle accelerator

1130 The LHC has always been considered as an option to the future of CERN. At the moment of the
1131 construction of the LEP beneath the border between France and Switzerland, the tunnel was built in
1132 order to accomodate what would be a Large Hadron Collider with a dipole field of 10 T and a beam
1133 energy in between 8 and 9 TeV [7] directly followed in 1985 with the creation of a 'Working Group
1134 on the Scientific and Technological Future of CERN' to investigate such a collider [8]. The decision
1135 was finally taken almost 10 years later, in 1994, to construct the LHC in the LEP tunnel [9] and the
1136 approval of the 4 main experiments that would take place at the 4 interaction points would come in
1137 1997 [10] and 1998 [11]:

- 1138 • ALICE [12] has been designed in the purpose of studying quark-gluon plasma that is believed
1139 to have been a state of matter that existed in the very first moment of the universe.
- 1140 • ATLAS [13] and CMS [14] are general purpose experiments that have been designed with
1141 the goal of continuing the exploration of the Standard Model and investigate new physics.
- 1142 • LHCb [15] has been designed to investigate the preference of matter over antimatter in the
1143 universe through the CP violation.

1144 These large scale experiments, as well as the full CERN accelerator complex, are displayed on
1145 Figure 2.4. The LHC is a 27 km long hadron collider and the most powerful accelerator used for
1146 particle physics since 2008 [16]. The LHC was originally designed to collide protons at a center-
1147 of-mass energy of 14 TeV and luminosity of $10^{34} \text{ cm}^{-2}\text{s}^{-1}$, as well as Pb ions at a center-of-mass
1148 energy of 2.8 TeV/A with a peak luminosity of $10^{27} \text{ cm}^{-2}\text{s}^{-1}$. Run 1 of LHC, when the center-of-
1149 mass energy only was half of the nominal LHC energy, was enough for both CMS and ATLAS to

discover the Higgs boson [17] and for LHCb to discover pentaquarks [18] and confirm the existance of tetraquarks [19]. Nevertheless, after the Third Long Shutdown (LS3) (2024-2026), the accelerator will be in the so called High Luminosity LHC (HL-LHC) configuration [20], increasing its instantaneous luminosity to $10^{35} \text{ cm}^{-2}\text{s}^{-1}$ for pp collisions and to $4.5 \times 10^{27} \text{ cm}^{-2}\text{s}^{-1}$, boosting the discovery potential of the LHC. The HL-LHC phase should last at least another 10 years depending on the breakthrough this machine would lead to. Already a new accelerating device, the FCC, as been proposed to prepare the future of high energy physics after the LHC.

CERN's Accelerator Complex

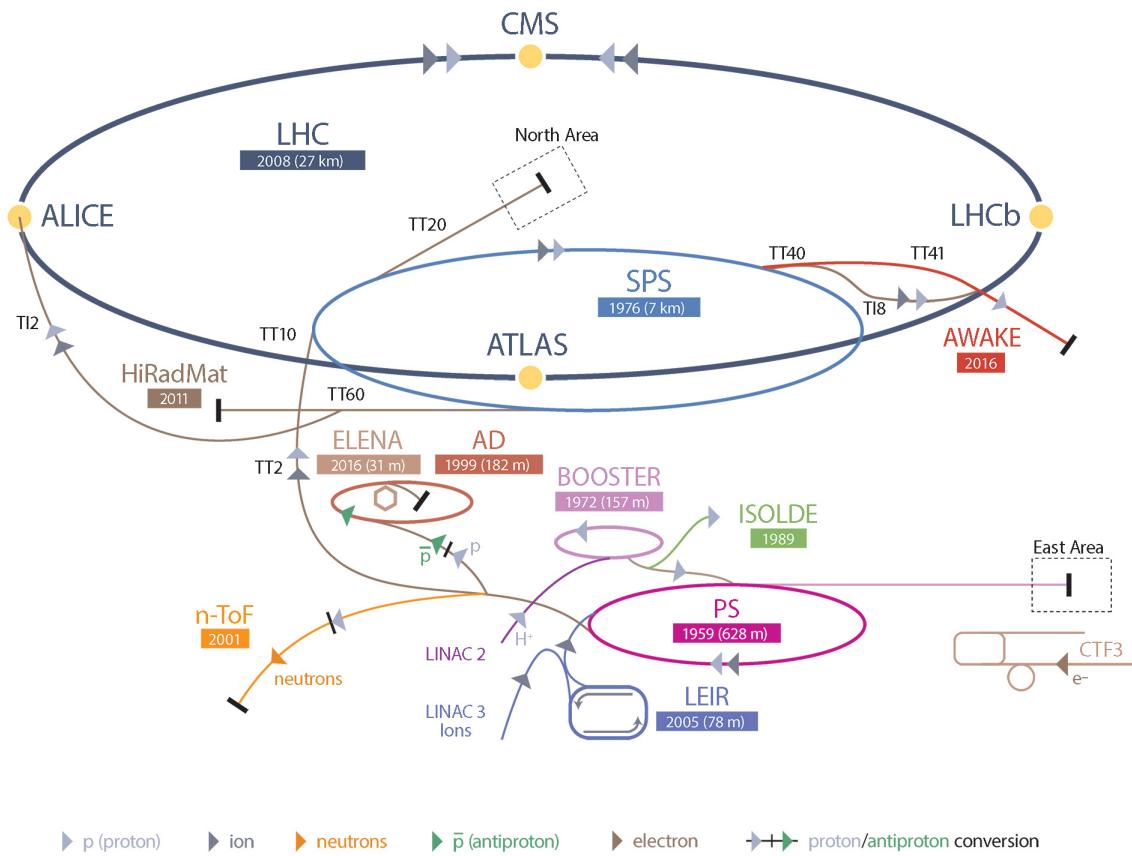

Figure 2.4: CERN accelerator complex.

2.2.1.1 Particle acceleration

The LHC is the last of a long series of accelerating devices. Before being accelerated by the LHC, the particles need to pass through different acceleration stages. All these acceleration stages are visible on Figure 2.4 and pictures of the accelerators are showed in Figure 2.5.

The story of accelerated protons at CERN starts with a bottle of hydrogen gas injected into the source chamber of the linear particle accelerator *LINAC 2* in which a strong electric field strips the

1164 electron off the hydrogen molecules only to keep their nuclei, the protons. The cylindrical conductors,
 1165 alternatively positively or negatively charged by radiofrequency cavities, accelerate protons by
 1166 pushing them from behind and pulling them from the front and ultimately give them an energy of
 1167 50 MeV, increasing their mass by 5% in the process.

1168

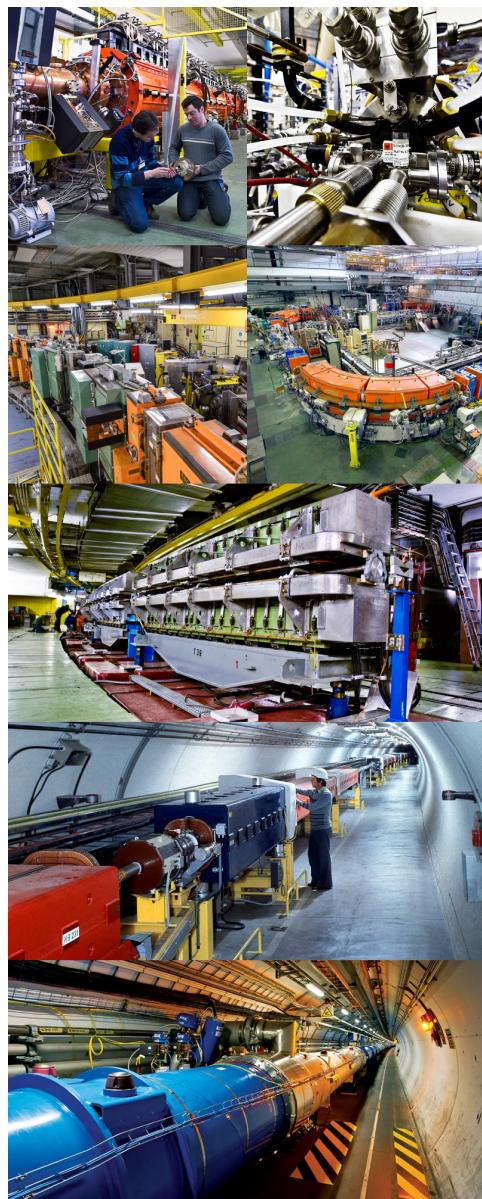

Figure 2.5: Pictures of the different accelerators. From top to bottom: first the LINAC 2 and the Pb source of LINAC 3. Then the Booster and the LEIR. Finally, the PS, the SPS and the LHC.

1169 When exiting the LINAC 2, the protons are divided into 4 bunches and injected into the 4 superimposed
 1170 synchrotron rings of the *Booster* where they are then accelerated to reach an energy of

1171 1.4 GeV before being injected into the PS. Before the Booster was operational in 1972, the protons
 1172 were directly injected into the PS from the LINAC 2 but the low injection energy limited the amount
 1173 of protons that could be accelerated at once by the PS. With the Booster, the PS accepts approxi-
 1174 mately 100 times more particles.

1175

1176 The 4 proton bunches are thus sent as one to the PS where their energy eventually reaches
 1177 26 GeV. Since the 70s, the main goal of this 628 m circumference synchrotron has been to sup-
 1178 ply other machines with accelerated particles. Nowadays, not only the PS accelerates protons, it also
 1179 accelerates heavy ions from the *Low Energy Ion Ring (LEIR)*. Indeed, the LHC experiments are not
 1180 only designed to study *pp*-collisions but also *Pb*-collisions. Lead is first injected into the dedicated
 1181 linear collider *LINAC 3*, that accelerate the ions using the same principle than LINAC 2. Electrons
 1182 are striped off the lead ions all along the acceleration process and eventually, only bare nuclei are
 1183 injected in the LEIR whose goal is to transform the long ion pulses received into short dense bunches
 1184 for LHC. Ions injected and stored in the PS were aceelerated by the LEIR from 4.2 MeV to 72 MeV.

1185

1186 Directly following the PS, is finally the last acceleration stage before the LHC, the 7 km long
 1187 *SPS*. The SPS accelerates the protons to 450 GeV and inject proton in both LHC accelerator rings
 1188 that will increase their energy up to 7 TeV. When the LHC runs with heavy lead ions for ALICE
 1189 and LHCb, ions are injected and accelerated to reach the energy of 2.8 TeV/A.

1190

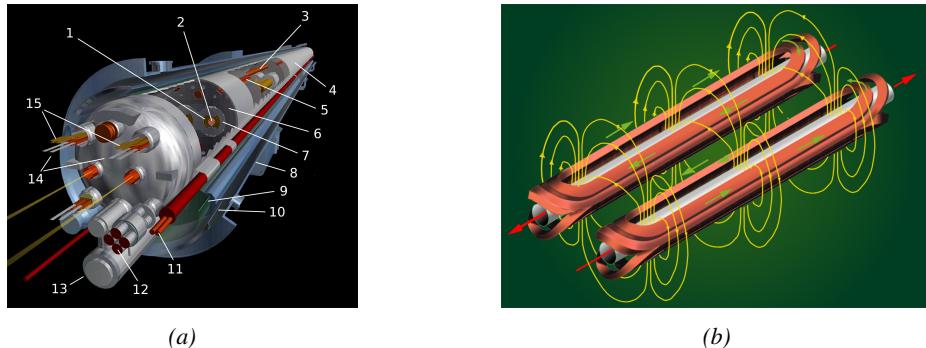

Figure 2.6: Figure 2.6a: schematics of the LHC cryodipoles. 1: Superconducting Coils, 2: Beam pipe, 3: Heat exchanger Pipe, 4: Helium-II Vessel, 5: Superconducting Bus-bar, 6: Iron Yoke, 7: Non-Magnetic Collars, 8: Vacuum Vessel, 9: Radiation Screen, 10: Thermal Shield, 11: Auxiliary Bus-bar Tube, 12: Instrumentation Feed Throughs, 13: Protection Diode, 14: Quadrupole Bus-bars, 15: Spool Piece Bus-bars. Figure 2.6b: magnetic field and resulting motion force applied on the beam particles.

1191

1192 The LHC beams are not continuous and are rather organised in bunch of paticles. When in *pp*-
 1193 collision mode, the beams are composed of 2808 bunches of 1.15×10^{11} protons separated by 25 ns.
 1194 When in *Pb* collision mode, the 592 *Pb* bunches are on the contrary composed of 2.2×10^8 ions
 1195 separated by 100 ns. The two parrallel proton beams of the LHC are contained in a single twin-
 1196 bore magnet due to the space restriction in the LEP tunnel. Indeed, building 2 completely separate
 1197 accelerator rings next to each other was impossible. The dipoles of the 1232 twin-bore magnets are
 1198 showed in Figure 2.6 alongside the magnetic field generated along the dipole section to accelerate the
 1199 particles. The dipoles generate a nominal field of 8.33 T, needed to give protons and lead nucleons
 their nominal energy. Some 392 quadrupoles, presented in Figure 2.7, are also used to focus to the

1200 beams, as well as other multipoles to correct smaller imperfections.

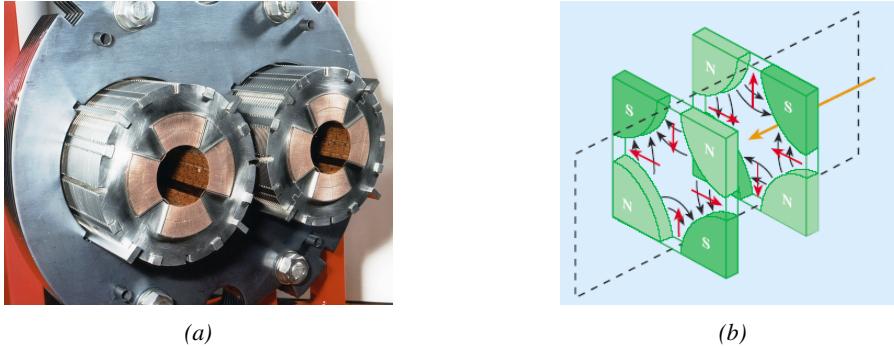

Figure 2.7: Figure 2.7a: picture of the LHC quadrupoles. Figure 2.7b: magnetic fields and resulting focussing force applied on the beam by 2 consecutive quadrupoles.

1201 2.2.2 CMS, a multipurpose experiment

1202 Among the four main LHC experiments is the Compact Muon Solenoid used as a multipurpose tool to
1203 investigate the SM and physics beyond its scope. Proposed through a letter of intention in 1992 [14],
1204 and as its name suggests, this very compact detector's uses the muons as a clear tag of most of SM
1205 and new physics interesting channels. In the original 1997 Technical Design Report (TDR) [21], the
1206 very first sentences were stating that "*Muons are an unmistakable signature of most of the physics*
1207 *LHC is designed to explore. The ability to trigger on and reconstruct muons at the highest lumi-*
1208 *nosities is central to the concept of CMS, the Compact Muon Solenoid.*" CMS participated in the
1209 discovery of the Higgs boson and the measurement of its properties and couplings together with
1210 ATLAS and is also actively involved in the search for SUSY and heavy ion collisions. Other exotic
1211 physics are also being investigated using the data collected by CMS.

1212 The CMS apparatus in itself is the heaviest detector ever built starring a SI15m diameter and a
1213 29 m length for a total weight of 14 kT. A thick 4 T solenoid magnet located at the beam interaction
1214 point hosts trackers and calorimeters. Extending in all directions around the magnet, heavy iron
1215 return yokes are installed to extend the magnetic field and support a muon system. The apparatus
1216 consists of a barrel, referring to the magnet and the detectors contained in it and the part of the muon
1217 system built directly in the cylinder around the magnet, and of 2 endcaps in the forward and back-
1218 ward region of the detector that closes the apparatus and complete the detection coverage along the
1219 beam line. A front view on the barrel is provided in Figure 2.8 while a detailed view of the apparatus
1220 is given in Figure 2.9.

1221

1222 In order to efficiently detect all long leaving particles and measure their properties with good
1223 precision, the CMS detector uses an onion like layout around of the interaction point in order to
1224 maximize the covered solid angle. As detailed in Figure 2.10, in the innermost region of the detector,
1225 closest to the interaction point, the silicon tracker records the trajectory of charged particles. Around
1226 it, the electromagnetic calorimeter (ECAL) stops and measure the energy deposition of electrons
1227 and photons. In the next layer, the hadron calorimeter (HCAL), hadrons are stopped and their energy
1228 measured. These layers are contained inside of the magnet of CMS, the superconducting solenoid.
1229 Outside of the magnet are the muon chambers embedded into iron return yokes used to control the

1230 magnetic field and gives muons, the only particles traveling completely through the whole detector, a
 1231 double bending helping in reconstructing their energy and trajectory. Note that photons and neutral
 1232 hadrons are differentiated from electrons and charged hadrons in the calorimeters by the fact that
 1233 don't interact with the silicon tracker and that they are not influenced by the magnetic field.

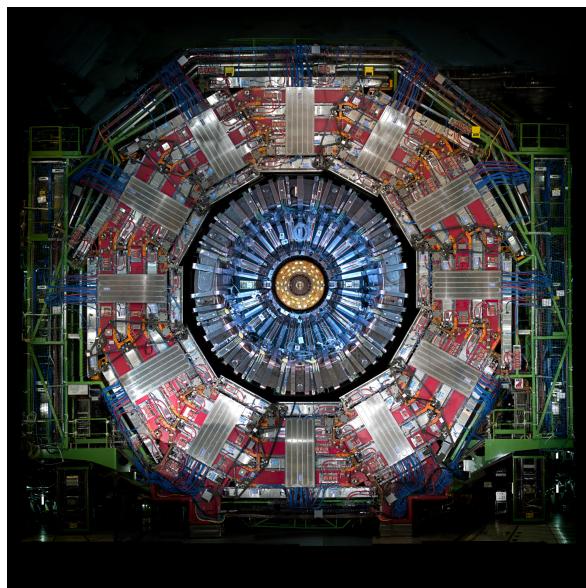

Figure 2.8: Picture of the CMS barrel. The red outer layer is the muon system hosted into the red iron return yokes. The calorimeters are the blue cylinder inside in magnet solenoid and the tracker is the inner yellow cylinder built around the beam pipe.

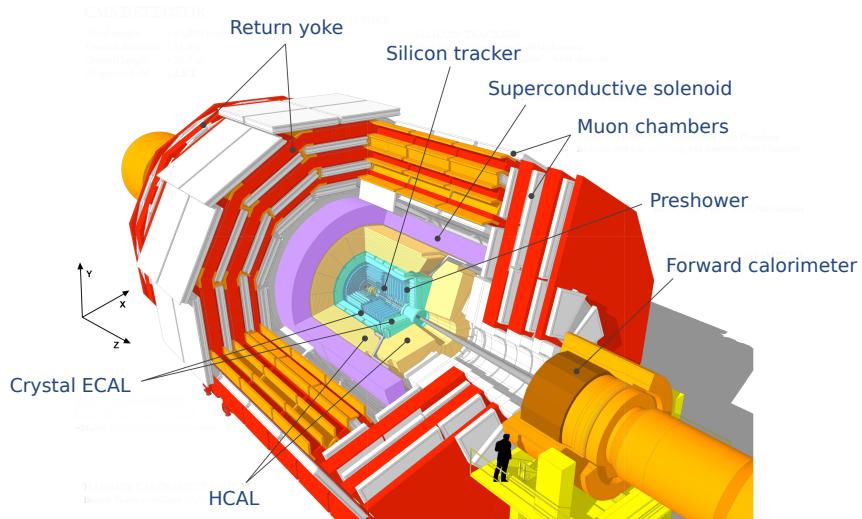

Figure 2.9: View of the CMS apparatus and of its different components.

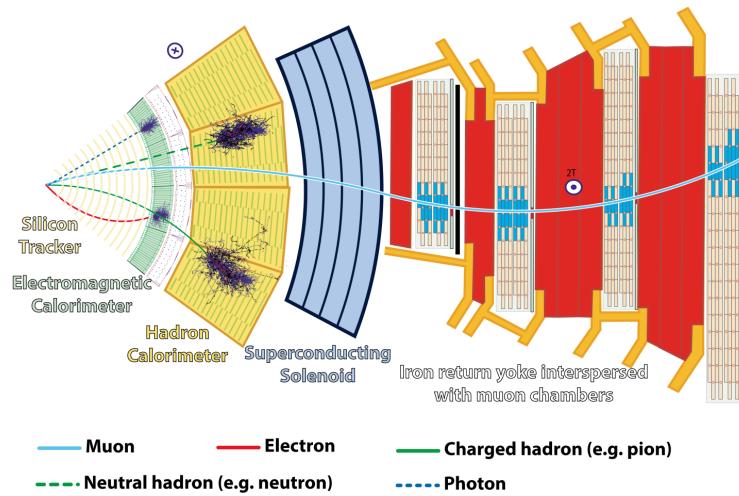

Figure 2.10: Slice showing CMS sub-detectors and how particles interact with them.

2.2.2.1 The silicon tracker, core of CMS

The silicon tracker visible on Figure 2.11 is divided into 2 different sub-systems: the *pixel detector* at the very core and the *microstrip detector* around it. This system is composed of 75 million individual readout channels with up to 6000 channels per squared centimeter for the pixels making it the world's biggest silicon detector. This density allows for measurements of the particle tracks with a precision of the order of $10\ \mu\text{m}$. This is necessary to reconstruct all the different interaction vertices with precision and have a precise measure of the curvature of the charged particles traveling through the magnetic field to estimate their charge and momentum.

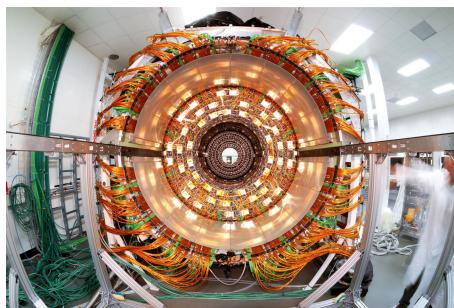

Figure 2.11: CMS tracker.

2.2.2.2 The calorimeters, measurement of particle's energy

The ECAL directly surrounding the tracker is composed of crystals of lead tungstate, PbWO_4 , a very dense but optically transparent material used to stop high energy electrons and photons. These crystal blocks basically are extremely dense scintillators which scintillate in fast, short light bursts proportionally to the energy deposition. The light is yielded rapidly and contained at 80% in the corresponding 25 ns lasting bunch crossing. Each crystal is isolated from the other by the carbon fiber matrix they are embedded in. It is composed of a barrel containing more than 60,000 crystals

1249 and of closing endcaps containing another 15,000 crystals. In front of the ECAL endcap is installed
 1250 a preshower detector made out of two layers of lead and silicon strip detectors to increase the spatial
 1251 resolution close to the beam line for pion-photon and single-double photon discrimination purposes.
 1252 Figure 2.12 shows the calorimeter inside of the magnet and the crystals.

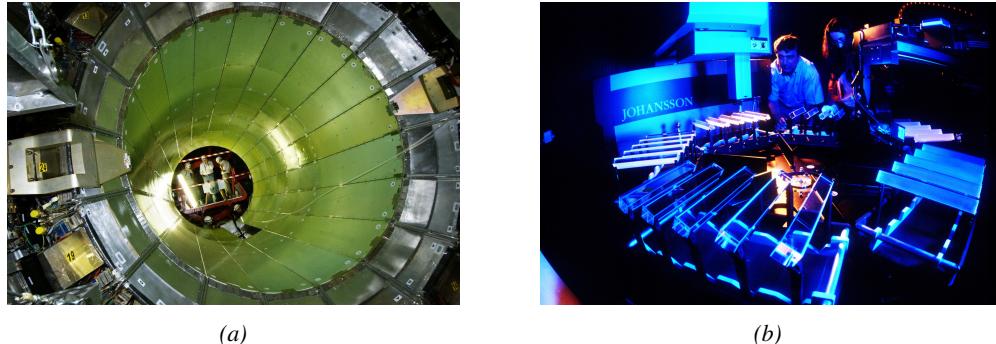

Figure 2.12: Figure 2.12a: picture of the ECAL. Figure 2.12b: picture of the lead tungstate crystals composing the ECAL.

1253 The next layer is the HCAL measuring the hadrons momentum and providing indirect hints of
 1254 non interacting neutral particles, such as neutrinos, as missing transverse momentum. Several layers
 1255 of brass or steel are interleaved with plastic scintillators readout by photodiodes using wavelength-
 1256 shifting fibers. The HCAL is also composed of a barrel, showed in Figure 2.13 and of endcaps. It
 1257 also features forward calorimeters on both sides of CMS in the region very close to the beam line at
 1258 high pseudorapidity ($3.0 < |\eta| < 5.0$). The role of these forward calorimeters, made using steel and
 1259 quartz fibers, is to measure very energetic hadrons.

Figure 2.13: CMS hadron calorimeter barrel.

1260 Finally, in the outer region of the apparatus, a muon system is used to trigger on potentially
 1261 interesting event by identifying muons. Indeed, the muon system is a very important part of the
 1262 CMS trigger infrastructure designed to efficiently select data from the enormous data flow received
 1263 by the detectors as the LHC delivers collisions at a rate of 40 MHz with a pile-ip of 20 to 30 collisions
 1264 per bunch crossing during Phase-I and up to 200 during Phase-II, representing billions of interactions
 1265 per second among which a large quantity are low energy collisions that are not likely to produce new
 1266 reactions, and which is physically impossible for nowadays technologies to cope with. Working at
 1267 a maximum rate of 100 kHz, the trigger system is able to select the 100,000 more interesting events

by looking at the energy distribution of the interaction products and clear signatures like muons reconstructed by the muon system. the vast majority of these events will not finally be stored after physics tests are applied.

2.2.2.3 The muon system, corner stone of CMS

The challenge for the muon system is to provide a robust and fast measurement of muons. Three different subsystems, and soon 4 after LS2, compose the muon system as showed in Figure 2.14 in which a quadrant of the CMS detector focused on muon system. Drift Tube (DT) are found in the barrel region covering the low pseudorapidity region where particles transverse momentum is lower and Cathode Strip Chamber (CSC) are found in the endcap region covering higher pseudorapidity region closer to beam line where particles have a stronger momentum. The redundancy of the system is insured by Resistive Plate Chamber (RPC) in both the barrel and endcap region. Nevertheless, the region closest to the beam line ($|\eta| > 1.8$) was not equipped with RPCs. This lack of redundancy in the high pseudo rapidity region will be solved during LS2, the following Year End Technical Stop (YETS) in 2021 and 2022, and LS3 where the necessary services, detectors and Link System, that collects the data and synchronizes them, will be installed.

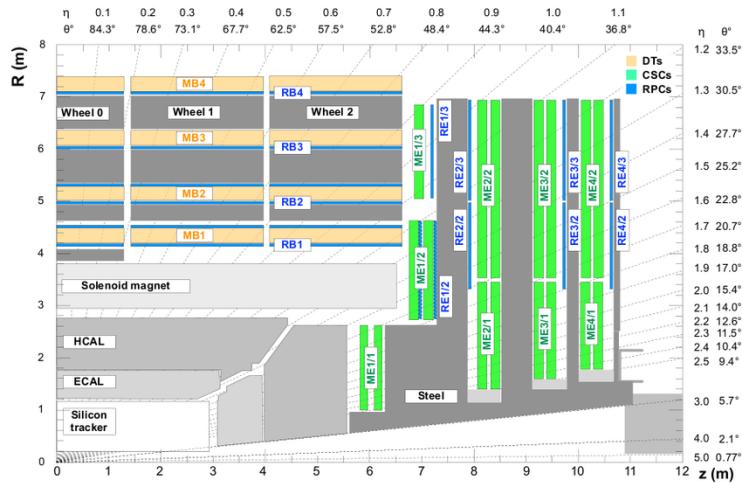

Figure 2.14: A quadrant of the muon system, showing DTs (yellow), RPCs (blue), and CSCs (green).

The barrel region is divided into 5 *wheels* made out of 4 *rings* of detectors with iron return yokes in between them whereas the endcaps are made out of 4 disks, each divided into pseudorapidity stations, 2 for CSCs (except for the first disk where 3 stations are equipped) and 3 for RPCs, although only 2 RPCs stations are equipped at present. The wheels and disks are showed in Figure 2.15. So far, each subsystem was dedicated to a particular task. DTs, in the barrel, and CSCs, in the endcaps, are used mainly for their spatial resolution. Indeed, DTs' resolution is of the order of 100 μm along both the $(r - \phi)$ and $(r - z)$ components while the resolution of CSCs is similar but varies in a range from 50 μm to 140 μm depending on the distance to the beamline. On the other hand, RPCs are used for their time resolution as they can deliver an information on the muon tracks within 1.5 ns.

The 250 CMS DTs, found in the barrel covering the pseudorapidity region $0 < |\eta| < 1.2$ and whose structure is shown in Figure 2.16, are composed of 3 *superlayers* of DT cells. Two of these superlayers are dedicated to measuring the ϕ coordinate of the muons and while the last one

measures the η (or z) coordinate. Each superlayer consists on 4 layers of 60 to 70 DT cells arranged in quincunx to allow for a precise reconstruction of the muon path through the DT layers. Each DT cell is a rectangular aluminium gas volume with a central anode wire. Cathode strips are placed on the narrow surface of the cells and electrode strips are placed on the wide surface to help shaping the electric field to ensure a consistent drift velocity of electrons in the drift volume. These detectors are operated using a 85/15 mixture of Ar and CO_2 .

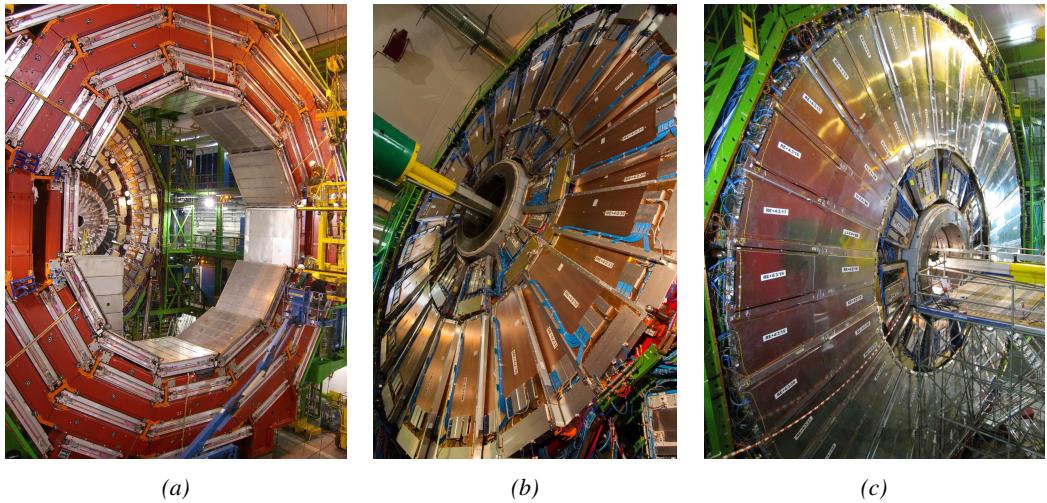

Figure 2.15: Figure 2.15a: Barrel wheel with its detector rings and return yokes. Figure 2.15b: CSC endcap disk with the 2 CSC stations. The outer station is made of 10 deg detectors while the inner station is made of 20 deg detectors. Figure 2.15c: RPC endcap disk. The inner station is not equipped and the inner CSC station can be seen.

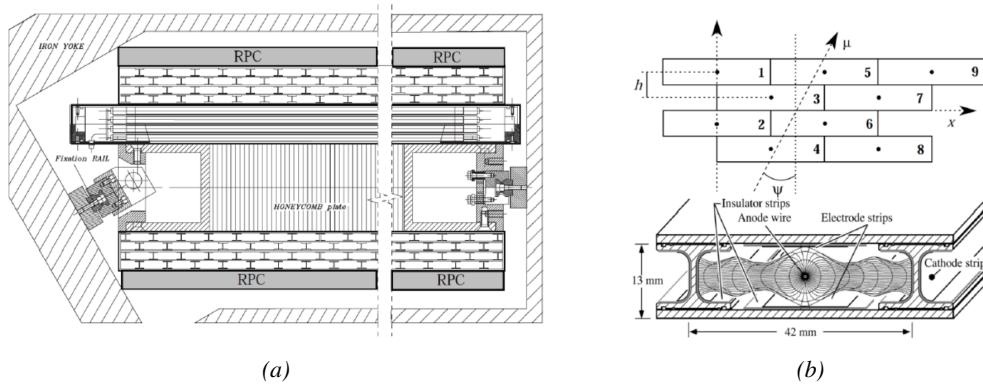

Figure 2.16: Figure 2.16a: Cross section of a DT module showing the two superlayers measuring the ϕ coordinate, perpendicular to the cross section plane, and the superlayer measuring the η coordinate, placed in between the two others with honeycomb and parallel to the cross section plane. The DT detector is sandwiched in between 2 RPCs whose readout strips are perpendicular to the cross section plane, measuring the ϕ coordinate. Figure 2.16b: A DT cell is shown together with its electric field. The path of a muon through a superlayer is shown.

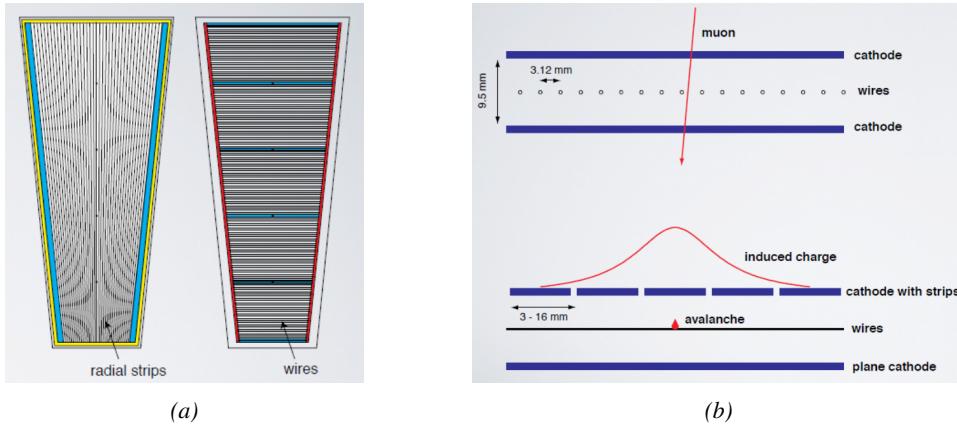

Figure 2.17: Figure 2.17a: cathode strips and anode wire layout of a CSC panel. Figure 2.17b avalanche development and charge collection by anode wires and induction on cathode strips inside of a CSC panel.

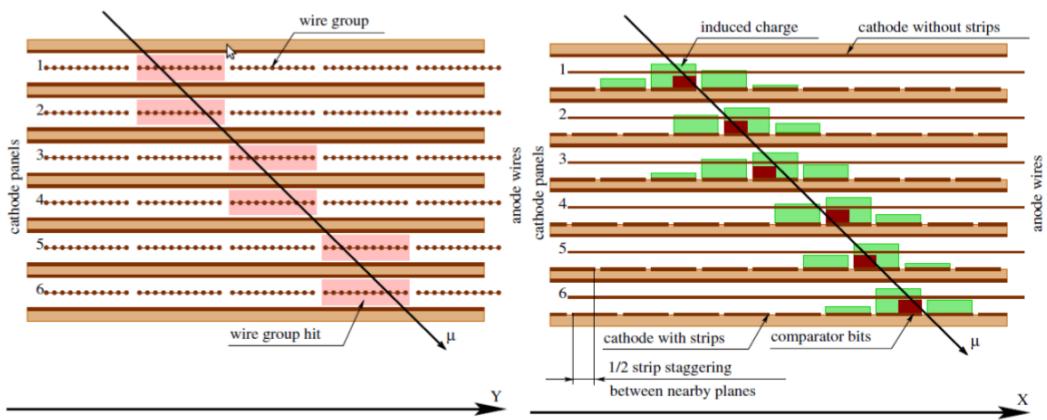

Figure 2.18: Muon track reconstruction through the 6 panels of a CMS CSC using the information of anode wire groups and cathode strip charge distribution combined with comparator bits to decide on which half strip the muon is more likely to have passed.

1301 The 540 CMS CSCs, found in the endcaps covering the pseudorapidity region $0.9 < |\eta| < 2.5$
 1302 and described through Figure 2.17, are composed of 6 panels of CSC, each panel consisting in
 1303 a wide gas volume of 9.5 mm (7 mm in the case of ME1/1 station) containing anode wires and
 1304 whose surfaces are cathodes. The top cathode is a wide copper plane of the size of the gas volume.
 1305 The bottom cathode is divided into thin trapezoidal copper strips radially arranged to measure the
 1306 azimuthal coordinate ϕ with a pitch ranging from 8 to 16 mm. The $0.50 \mu\text{m}$ anode wires are placed
 1307 perpendicularly to the strips to measure radial coordinate r and are grouped by 10 to 15 with a wire
 1308 to wire space of 3.2 mm. In the specific case of ME1/1 placed against the HCAL endcap, the $0.30 \mu\text{m}$
 1309 anode wires have a wire to wire distance of 2.5 mm and are not disposed perpendicularly to the strips
 1310 but slightly tilted by an angle of 29 deg to compensate for the lorentz force due to the very strong
 1311 local magnetic field of 4 T. These detectors are operated with a 40/50/10 mixture of Ar, CO₂ and
 1312 CF₄. Combining the information of the multiple CSC panels, the detectors achieve a very precise
 1313 measurement of the muon track.

Despite their excellent spatial resolution, the wire chambers (DTs and CSCs) are limited in terms of time resolution by the fact that the charge needs to drift towards the anode wire and be collected before having the confirmation that a particle was detected as the drift volume is not used to develop avalanches. Indeed, the stronger electric field close to the anode wire triggers the avalanche and the gain of the detector. Due to the drift, the time resolution is thus limited at best to approximately 2 to 3 ns. In addition, even though the intrinsic time resolution of the tracking chambers is rather good compared to the 25 ns in between successive collisions, the processing time of the trigger system doesn't allow for very fast triggering as it provides a time precision of only 12.5 ns. Thus, detectors fully dedicated to timing measurement have been installed as a redundant system. These detectors are RPCs, also gaseous detectors but that use current induction instead of charge collection allowing for a time resolution of the order of 1.5 ns only. Theoretically, depending on the design used, RPCs could reach a time resolution of the order of 10 ps but in the context of LHC where bunch crossing happen every 25 ns, a time resolution of 1.5 ns is sufficient to accurately assign the right bunch crossing to each detected muon.

The 1056 RPCs equipping the CMS muon system both in the barrel and endcap regions and covering the pseudorapidity region $0 < |\eta| < 1.6$ are composed of two layers of RPC *gaps* as described in Figure 2.19. Each gap consists in two resistive electrodes made out of 2 mm thick Bakelite enclosing a 2 mm thick gas volume containing a 95.2/4.5/0.3 mixture of $C_2H_2F_4$, $i - C_4H_{10}$ and SF_6 . Due to this geometry, the electric field inside of a gap is homogeneous and linear at every point in the gas translating into a uniform development of avalanches in the gas volume as soon as a passing muon ionises the gas. The two gaps sandwich a readout copper strip plane. A negative voltage is applied on the outer electrodes, used as cathodes, and the inner electrodes, the anodes, are simply connected to the ground as well as the readout panel that picks up the current induced by the accumulated charge of the growing avalanches in one or both of the gas gaps. This OR system allows for a lower gain (i.e. a lower electric field) on both gaps to reach the maximal efficiency of such a detector.

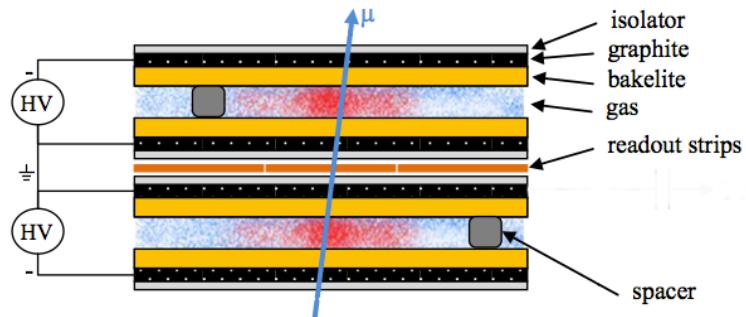

Figure 2.19: Double gap layout of CMS RPCs. Muons passing through the gas volumes will create electron-ion pairs by ionising the gas. this ionisation will immediately translate into a developing avalanche.

3

1340

1341

Muon Phase-II Upgrade

1342 The very first proton beam successfully circulated in the LHC in September 2008 directly followed
1343 by an incident leading to mechanical damage that would delay the LHC program for a year until
1344 November 2009, the very first collisions at a center-of-mass energy of 7 TeV taking place in March
1345 2010. The energy of the beam would be increased after a First Long Shutdown (LS1) starting early
1346 2013 after less than 3 years of data taking. Nevertheless, this first data taking period at only 7 TeV
1347 was sufficient to claim the discovery of a new particle compatible with the Higgs boson in July 2012.
1348 During the 2 years of shutdown, the upgrade of the accelerator allowed for several maintainances
1349 along the beam pipes, repair and consolidation of magnet connection and high-current splices. But
1350 not only the LHC was upgraded. Indeed, the experiments at the 4 collision points also took the
1351 advantage of this time to upgrade their system in prevision of the next LHC run (Run-II) until
1352 2018 and the Second Long Shutdown (LS2) as the luminosity and energy of the beam would be
1353 continuously increasing. By the end of Run-II, the luminosity will have reached twice its nominal
1354 value when the center-of-mass energy has already got close to its nominal value by reaching an
1355 historical 13 TeV for the first time in 2017.

1356 The next long shutdown will occur at the end of this year and will again be the occasion for sim-
1357 ilar maintenance and consolidation in prevision of Run-III and the future upgrade of LS3. Still, the
1358 main occupation of LS2 on LHC side will be the upgrade of LHC injectors. On the experiments side,
1359 LHCb and ALICE will, in a very tight schedule, implement major upgrades while ATLAS and CMS
1360 will wait until LS3 to upgrade their detectors in prevision of high luminosity *LHC-Phase-II*. ALICE
1361 main challenge is an upgrade of their apparatus to cope with the 50 kHz $Pb - Pb$ collisions. Simi-
1362 larly, LHCb will upgrade their frontend readout electronics to cope with the full 40 MHz collisions
1363 delivered by LHC. ATLAS will perform standard maintenance and CMS will focus on the urgent up-
1364 grade of the pixel detector and on the installation of new muon detectors in order to take profit of LS2
1365 time to mitigate the upgrade of detectors foreseen during LS3. Run-III will start in 2021 with the LHC
1366 at its nominal center-of-mass energy and will bring LHC-Phase-I to an end at the end of 2023. By
1367 then the luminosity will only increase to reach 2.5 times the nominal luminosity but during these 3
1368 years of run, the LHC will deliver as much integrated luminosity as what what brought during the al-

¹³⁶⁹ most 7 years of both Run-I and II of data taking. Phase-I will end with an overall 300 fb^{-1} delivered.
¹³⁷⁰

¹³⁷¹ 3.1 High Luminosity LHC and muon system requirements

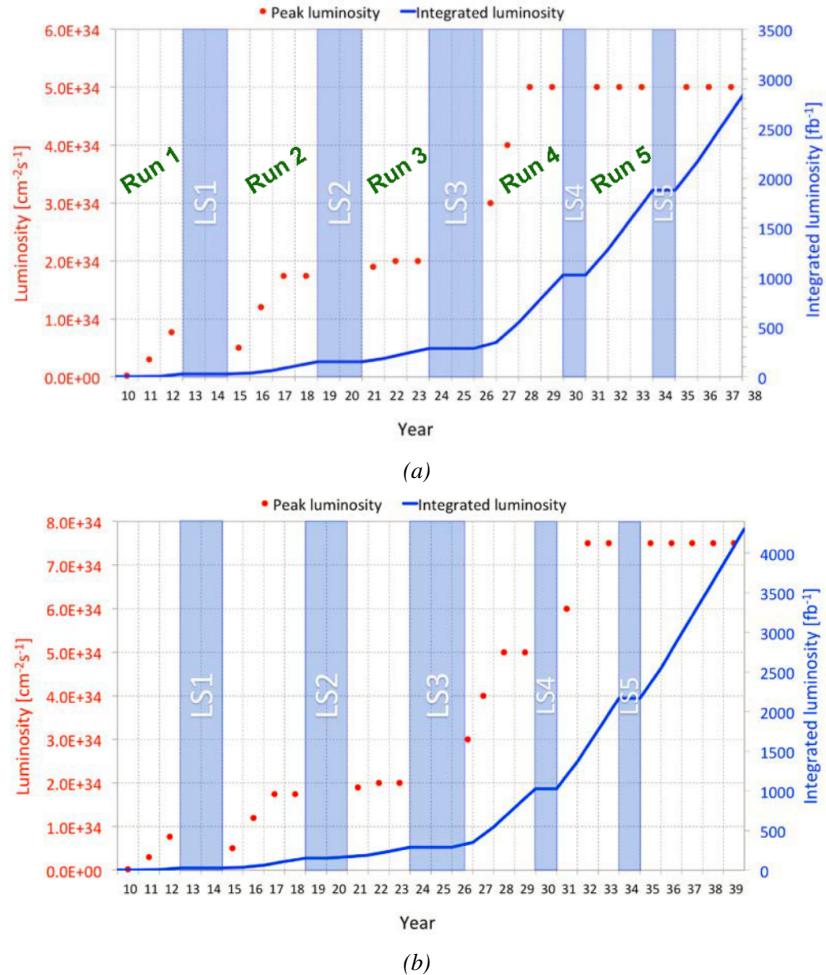

Figure 3.1: Detailed timeline projection of for LHC and HL-LHC operation until 2039 showing the evolution of the instantaneous and integrated luminosity as designed (Figure 3.1a) and in the ultimate case where the instantaneous luminosity is increased to $7.5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ (Figure 3.1b) [20, 22].

¹³⁷² After approximately 15 years of operation, the LHC will undergo a new series of upgrade during
¹³⁷³ the LS3 in order to boost its discovery potential as showed in Figure 3.1. This moment onward is
¹³⁷⁴ what is referred to HL-LHC or Phase-II. The goal is to aim for a luminosity 5 to 7 times stronger
¹³⁷⁵ than the nominal one trying to reach even 10 times this value if possible. Increasing the luminosity
¹³⁷⁶ means that the beam size at the collision points needs to be reduced to boost the number of collisions
¹³⁷⁷ per bunch crossing. For this purpose, new focusing and bending magnets, and collimators will be
¹³⁷⁸ installed at the collision points as well as newly developed "crab cavities" that will tilt the particle

1379 bunched just prior to the collisions by giving them transverse momentum and thus increasing their
 1380 meeting area. In addition, the full proton injection line will be upgraded.

1381 Over its full lifetime, the HL-LHC is expected to deliver an outstanding integrated luminosity of
 1382 3000 fb^{-1} leading, in the case of Higgs studies to measuring the couplings of the boson to a precision
 1383 of 2 to 5% thanks to the estimated 15 millions of Higgs created every year providing a more precise
 1384 measurement of potential deviations from the theoretical predictions. SUSY and heavy gauge boson
 1385 studies would also see their mass range limits pushed away by at least 1 TeV and could lead to a new
 1386 breakthrough. SUSY is a particularly important topic as it could give an answer to why the Higgs
 1387 boson can stay so light while coupled to heavy particles by introducing the contributions of the super
 1388 partners on top of providing dark matter candidates. Finally, the increase of luminosity will give the
 1389 possibility to investigate "exotic" mode like for example the models introducing extra dimensions to
 1390 explain the hierarchy problem.

1391 On the experiments side, the pile-up (PU) will be increased up to 150 to 200 interactions per
 1392 bunch crossing in ATLAS and CMS, making necessary an strong upgrade of the trigger system and
 1393 of the inner trackers and of the calorimeters. Both ATLAS and CMS will also need to upgrade
 1394 the muon trigger at the level of the endcaps mainly focusing on the coverage near the beam line in
 1395 order to increase the detection acceptance and event selection. Moreover, the increased luminosity
 1396 will also lead to an increased background rate and a faster ageing of the detectors. This PhD work
 1397 takes place into this very specific context of muon detector consolidation and certification for the
 1398 HL-LHC period in order to provide the CMS experiment with robust new detectors and confirm that
 1399 the present system will survive through the next 20 years of HL-LHC.

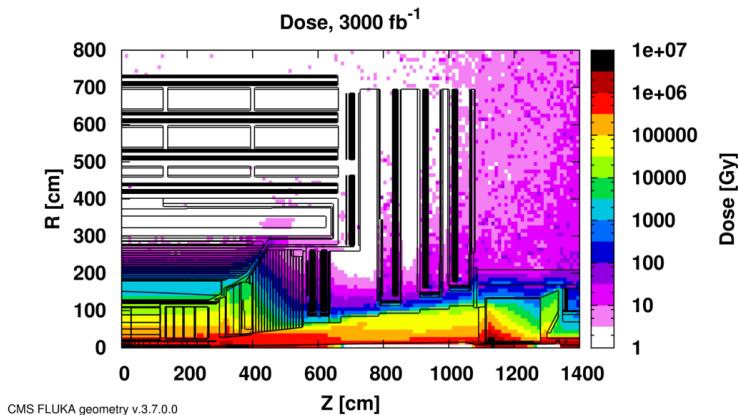

Figure 3.2: Absorbed dose in the CMS cavern after an integrated luminosity of 3000 fb . Using the interaction point as reference, R is the transverse distance from the beamline and Z is the distance along the beamline.

1400 The end of 2018 will mark the beginning of LS2 and the start of Phase-II upgrade activities.
 1401 From the HL-LHC period onwards, i.e. past LS3, the performance degradation due to integrated
 1402 radiation as well as the average number of inelastic collisions per bunch crossing, seen as pile-up
 1403 into the detectors' readout that far exceeds this of the original LHC plans, will rise substantially and
 1404 become a major challenge for all of the LHC experiments, like CMS, that were forced to address
 1405 an upgrade program for Phase-II [23]. Dealing with the data from the muon detectors will force
 1406 to upgrade the detectors and electronics towards the most recent technologies. Simultaneously, this
 1407 will push new latency requirements onto the Level-1 trigger and the Data Acquisition (DAQ) that

will only be fulfilled by upgrading the system with electronics having deeper buffering and faster processing. Simulations of the expected distribution of absorbed dose in the CMS detector under HL-LHC conditions show, in Figure 3.2, that detectors placed close to the beam line will have to withstand high irradiation, the radiation dose being of the order of a few tens of Gy.

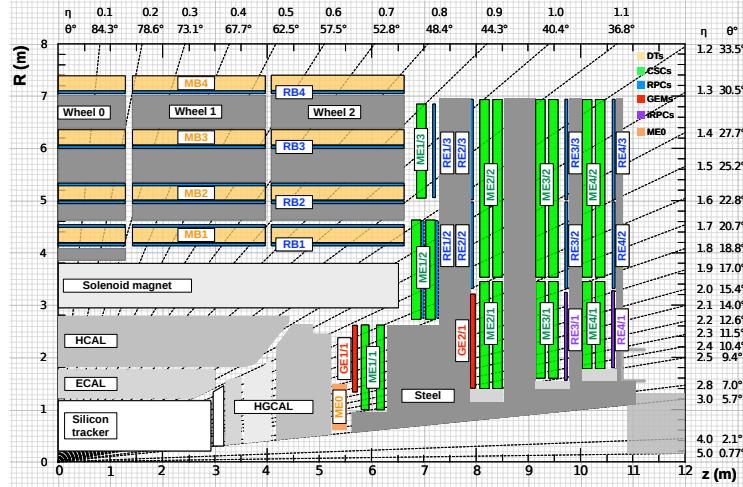

Figure 3.3: A quadrant of the muon system, showing DTs (yellow), RPCs (blue), and CSCs (green). The locations of new forward muon detectors for Phase-II are contained within the dashed box and indicated in red for GEM stations (ME0, GE1/1, and GE2/1) and dark blue for improved RPC (iRPC) stations (RE3/1 and RE4/1).

The increase of irradiation close to the beam line will affect the background rate seen by the muon detectors in this area and tracking muons will prove to be difficult as this region is not yet equipped with all the detectors that were already foreseen for Phase-I. Improving this situation will come with the increase of hit numbers recorded along the particle track to reduce the ambiguity on muon versus background detection. Moreover, the measurement of small production cross-section and/or decay branching ratio processes, such as the Higgs boson coupling to charge leptons, and in particular to muons, or the $B_s \rightarrow \mu^+ \mu^-$ decay, is of major interest and specific upgrades in the forward regions of the detector will be required to maximize the physics acceptance to the largest possible solid angle.

To ensure proper trigger performance within the present coverage, the muon system will be completed with new chambers and the electronics of the present system will need to be upgraded to ensure an efficient triggering. Figure 3.3 shows the addition of Gas Electron Multiplier (GEM) and improved RPC (iRPC) in the pseudo-rapidity region $1.6 < |\eta| < 2.4$ to complete the redundancy of the already existing CSCs as originally scheduled in the CMS Technical Proposal [24]. A first step into this direction will be taken by installing GEMs on the first endcap disk in position GE1/1 during LS2, during which preparations for the future installation of more GEMs and RPCs will take place by installing the needed services. During the YETS following LS2, iRPCs will be installed on the third and fourth endcap disks in position RE3/1 and RE4/1, and more GEMs will equip the second endcap in position GE2/1 and the inner layer, closest to the HCAL endcap called ME0 during LS3, finally completing the redundant coverage of the muon system and extending it a little by extending the reach to $|\eta| = 2.8$, the redundancy in the region $2.4 < |\eta| < 2.8$ being maintained by the 6 GEM layers contained in each ME0 detector that provide enough tracking points to efficiently reject

1434 neutron-induced background.

1435 Nevertheless, the region beyond $|\eta| > 2.8$ and extending to $|\eta| = 5.0$ only is covered by the
 1436 forward HCAL detectors and lack redundant muon detector coverage. Extensions of the tracker in
 1437 the context of HL-LHC will increase its coverage up to $|\eta| = 4.0$ but the identification of muons and
 1438 measurement of their energy with reasonable precision only using the tracker is nearly impossible.
 1439 Thus, this increased tracker coverage range needs to be put in parallel with a matching muon detector
 1440 and will open doors to multi-lepton final states in which leptons are likely to have a low transverse
 1441 momentum and to be found near the beam line.

1442

1443 Finally, as the muon system is composed only of gaseous detectors, strong environmental con-
 1444 cerns have risen over the last years as the European directives will restrict the use of fluorine based
 1445 gas mixtures. Both the CSC and RPC subsystems, using CF_4 , $C_2H_2F_4$, or SF_6 , will need to adapt
 1446 their working gas in order to strongly reduce the greenhouse potential of the mixtures released into
 1447 the atmosphere due to gas leaks.

1448 3.2 Necessity for improved electronics

1449 Drift Tubes and Cathode Strip Chambers are important components used to identify and measure
 1450 muons, especially thanks to their spatial resolution of the order of $100\text{ }\mu\text{m}$. Nevertheless, the lumi-
 1451 nosity and irradiation during HL-LHC will cause serious event loss and ageing on the electronics of
 1452 these subsystems that will comprise the triggering and data transferring needs of CMS. Thus, elec-
 1453 tronics upgrade are foreseen to address these expected problems. While only the RPCs' electronic
 1454 system is able to operate under Phase-II requirements, DTs and CSCs will need to improve their
 1455 trigger accept rate and latency to ensure that Level-1 trigger threshold stays at the same level [25],
 1456 and DAQ data transfer rate, that respectively need to achieve a minimum of 500 kHz , get down to
 1457 $12.5\text{ }\mu\text{s}$ [26], and increase to 1082 Gbit/s DTs and to 1026 Gbit/s for CSCs. As of today, the Level-
 1458 1 trigger accept rate of DTs doesn't reach 300 kHz while this of CSCs is below 250 kHz but the
 1459 foreseen upgrades are expected to increase the rate way beyond the requirement in the of DTs and
 1460 up to 4 MHz for CSCs [23].

1461 The first version of Minicrate electronics (MiC1) used by DTs don't allow for high enough
 1462 trigger rate. In addition to this problem, it was showed that these electronics contain components
 1463 that are not radiation hard enough to sustain HL-LHC conditions and thus, a too large number of
 1464 channels may fail due to radiations. Considering the most optimistic scenario, at least 19% of the
 1465 channels could have failed by LS4, as explicitated in Figure 3.4, far before the end of the HL-LHC
 1466 campain. The MiC1 will be replaced on each detector by an improved version referred to as MiC2
 1467 while front-end electronics and high-voltage modules will not need any replacement. On the other
 1468 hand, CSCs showed that there electronics would be able to live through the 10 years of Phase-II but
 1469 the limited buffer depth might cause memory overflows and readout inefficiencies with a fraction
 1470 of event loss ranging from 5 to more than 10% at an instantaneous luminosity similar to which of
 1471 HL-LHC depending on the expected background, as showed on Figure 3.5 through the different
 1472 detector positions. Thus the replacement of CSCs' cathode front-end boards (CFEBs) by digital
 1473 ones, DCFEBS, with deeper buffer would permit to make event loss negligible and satisfy HL-LHC
 1474 requirements [23].

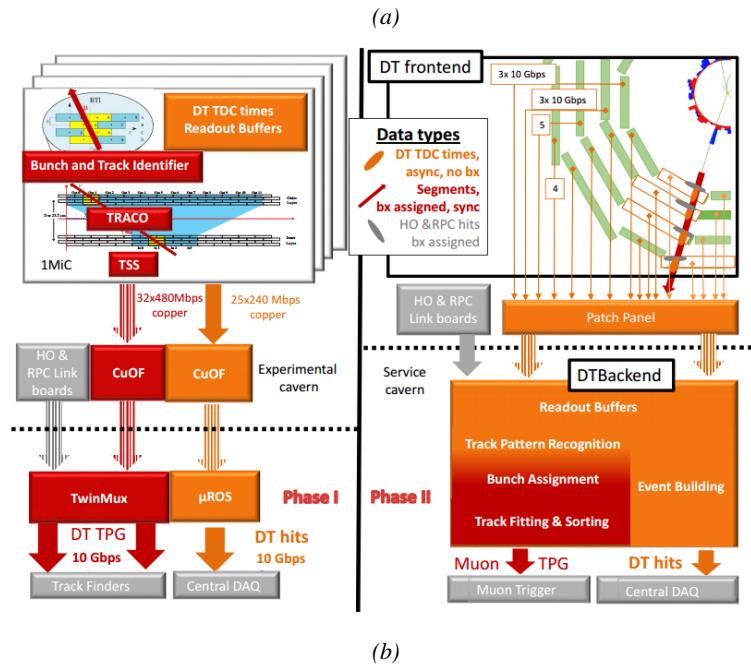

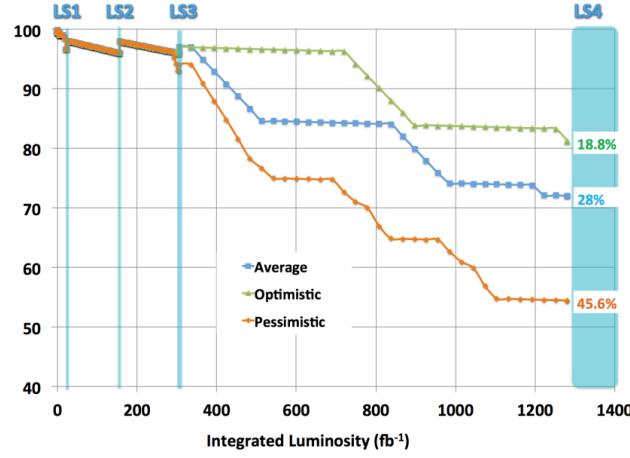

Figure 3.4: Figure 3.4a: Extrapolated fraction of failing channels of the present DT MiC1 electronics as a function of the integrated luminosity for different scenari until LS4. Figure 3.4b: Comparison of the current (left) and upgraded (right) DT data processing. So far, the data is sent to service cavern of CMS facility via copper-to-optical-fiber translators (CuOF) by each MiC1. There, data including RPCs and outer hadron calorimeter is combined into trigger primitives (TPG) and transmitted by the TwinMux system to CMS Track Finder. The time-to-digital converter (TDC) data is collected and sent to the CMS data acquisition system (DAQ) by the micro read-out server (μ ROS). After the upgrade, the TDC data will be sent via optical links to a patch panel inside the experimental cavern by each MiC2, and transferred to the back-end, where triggering and event building will be performed.

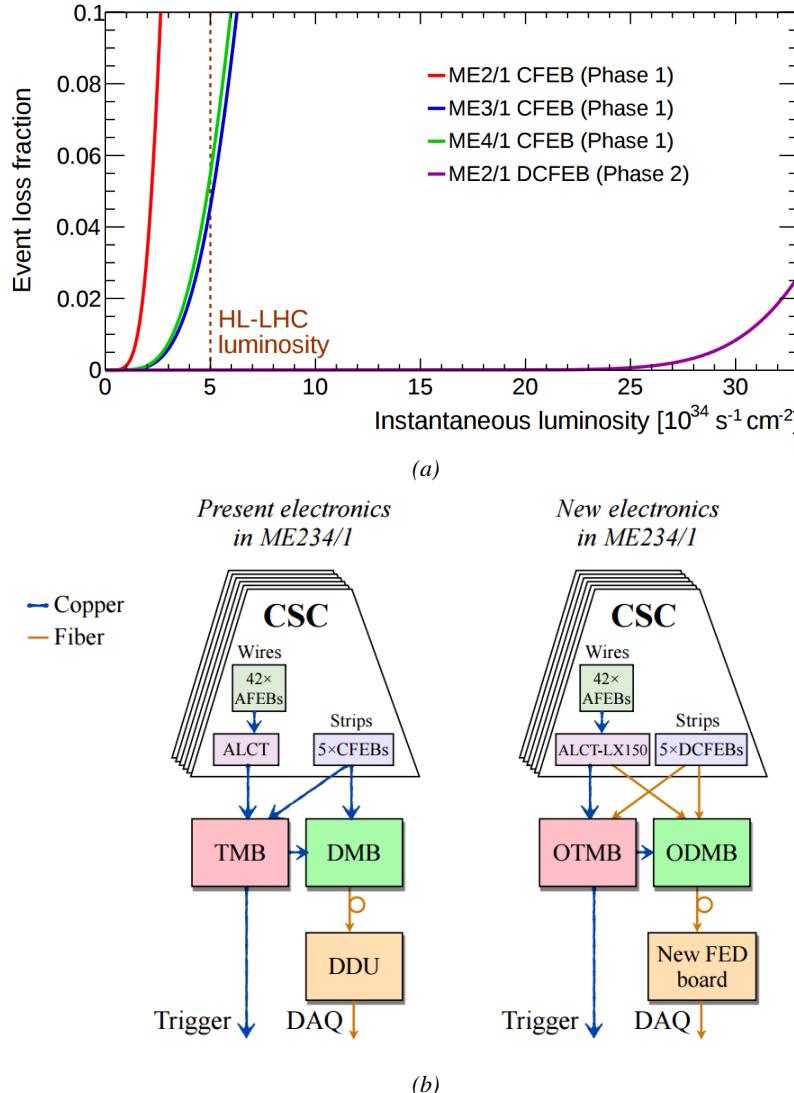

Figure 3.5: Figure 3.5a: The event loss fractions as a function of the instantaneous luminosity is compared for CFEBs (Phase-1) and DCFEBs (Phase-II) at different CSC locations. HL-LHC luminosity is marked with the dashed brown line. Figure 3.5b: Comparison of the current (left) and upgraded (right) CSC data processing. A part of the connections in between ALCTs and DCFEBs, and the trigger mother boards (TMBs) and data acquisition mother boards (DMBs) will be upgraded toward optical data transfer. The detector dependent units (DDUs) used as interface in between CSCs' front-end electronics and the CMS DAQ will be replaced by new FED boards.

All these new DT and CSC electronics will be connected to the trigger electronics via optical links to ensure a faster communication. The main change will come from the new DT minicrate modules which will not anymore be responsible for trigger and event building logic which will be transferred to the back-end electronics instead located in the service cavern via the patch pannels to which the Time-to-Digital Converter (TDC) data will be sent. The trigger and data transfer logic will barely change for CSCs. The existing copper cable connections of cathode and anode FEBs (CFEBs,

and AFEBs which data is transmitted through the ALCTs) toward the trigger and data mother boards (TMBs and DMBs) will simply be replaced by optical fibers and the TMBs and DMBs upgraded with optical versions (OTMBS and ODMBs). As a new feature, the full anode wire data from ALCTs will be sent to the ODMBs causing a lack of FPGA memory resources in these ALCT boards that will thus need replacement.

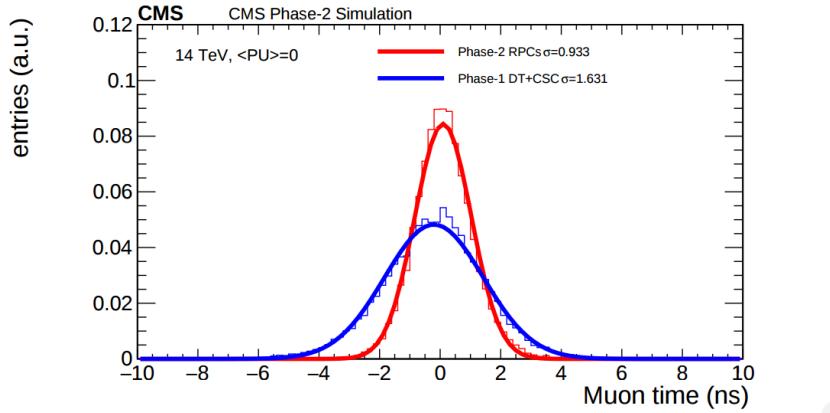

Figure 3.6: Comparison of the simulated time residuals in between reconstructed and true muon times without (blue) and with (red) the upgraded RPC link system.

The upgrade on the side of Resistive Plate Chambers will then not come from their on-board electronics but from the Link System located in the service cavern of CMS and that connects the front-end electronics data of RPCs into CMS trigger processors. The main motivation for such an upgrade is that the electronic board composing the link system are built using obsolete components and weak components that can easily suffer from the electromagnetic noise. These components may be the source of failing channels throughout Phase-II. Moreover, these link boards were originally designed only to match RPC digitized signals with the corresponding bunch crossing. Due to this feature, the time resolution of the full RPC chain is thus limited to 25 ns and does not exploit the full time resolution of the detectors. This would make the synchronization of the RPC system easier and allow to have a finer offline background removal within the 25 ns in between bunch crossings thanks to the order of magnitude gained in terms of time resolution.

Upgrading RPC link system will require the installation of 1376 new link boards and 216 control boards. The new boards will make use of the recent progress made with fast FPGAs and will be a great improvement to the ASICs formerly used as they will be able to process signals from several detectors in parallel. The benefit from using the full RPC time resolution thanks to the upgraded link system can be seen through Figure 3.6 where the resolution of the RPC system itself is better than that of DTs and CSCs that was used until now.

3.3 New detectors and increased acceptance

In the present muon system, the redundancy of was assured by RPCs used for their good timing performances. The extension of the muon system towards higher pseudo-rapidity in order to complete the redundancy in this very region and to contribute to the precision of muon momentum measurements will require muon chambers with a spatial resolution less or comparable to the contribution

1508 muon of multiple scattering through the detector volume [21]. Most of the plausible physics is
 1509 covered only considering muons with $p_T < 100$ GeV thus, in order to match CMS requirements,
 1510 a spatial resolution of $\mathcal{O}(\text{few mm})$ will be necessary for the proposed new RPC stations while the
 1511 GEMs will need a resolution better than 1 mm, as showed by the simulation in Figure 3.7.

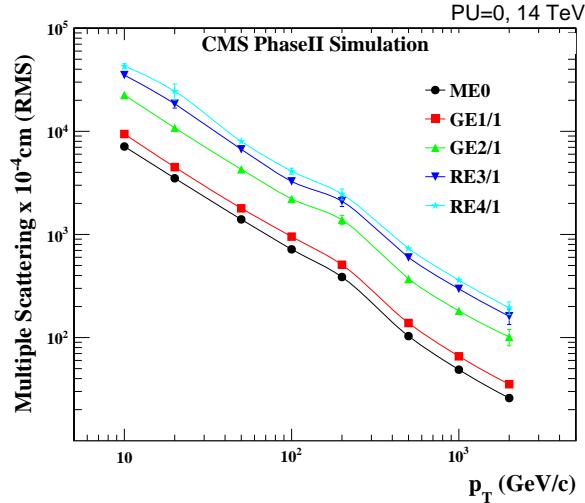

Figure 3.7: RMS of the multiple scattering displacement as a function of muon p_T for the proposed forward muon stations. All of the electromagnetic processes such as bremsstrahlung and magnetic field effect are included in the simulation.

1512 3.3.1 Improved forward resistive plate chambers

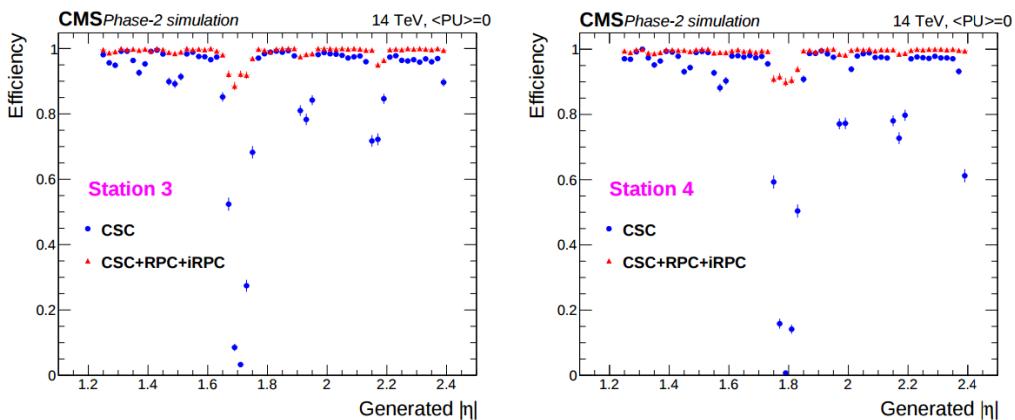

Figure 3.8: Simulation of the impact of RPC hit inclusion onto the local trigger primitive efficiency in station 3 (left) and station 4 (right). The contribution of iRPC starts above $|\eta| = 1.8$.

1513 Figure 3.3 shows that the iRPCs that will equip the third and fourth endcap disks in position RE3/1
 1514 and RE4/1 will finally be the partners of the CSCs in position ME3/1 and ME4/1 and complete
 1515 Phase-I plans but bringing the needed upgrades in the scope of Phase-II as the older chambers are

not suitable to equip the forward region of CMS due to HL-LHC rates and charge deposition. By completing the redundancy, more track along the muon trajectory will be available and the lever arm will be improved. The benefits from extending the redundancy of the muon system with iRPCs to the forward most region is showed in Figure 3.8 in which the trigger efficiency is showed with and without RPCs in which it is possible to see that the efficiency of CMS trigger with the complete redundancy is improved is above 95% in the region $|\eta| > 1.8$ as the iRPCs help filling the holes in the CSC system.

1523

The detectors that will be installed in the coming years will be similar to the already existing RPC system. 18 of the new chambers, each spanning 20° in φ around the beam axis with 96 radially oriented trapezoidal read-out strips, will cover each muon endcap disk leading to the production of 72 iRPCs. The main difference with the old RPC chambers is that these detectors will not have readout strips segmented in η as by using fast front-end electronics the strips will be read-out on both sides allowing for a radial spatial resolution of the order of 2 cm in order to contribute to the better reconstruction of muon in the forward region where the bending of muons by the magnetic field is low. This is motivated by the fact that, in the case a η segmentation was used, at least 5 pseudorapidity partitions would have been necessary to reach the minimal radial spatial resolution (≈ 20 cm). Having only one strip read-out from both along the chamber reduces by 60% the total number of channels and the necessary cabling and allows for a better spatial resolution. The strip pitch will range from 6.0 mm (5.9 mm) on the high pseudo-rapidity end to 12.3 mm (10.9 mm) on the low one on position RE3/1 (RE4/1). The spatial resolution in the direction perpendicular to the strips should reach approximately 3 mm, better than the minimal needed resolution (Figure 3.7), and the overall time resolution of the new installation will be equally 1.5 ns, as for the present due to the same link system being used.

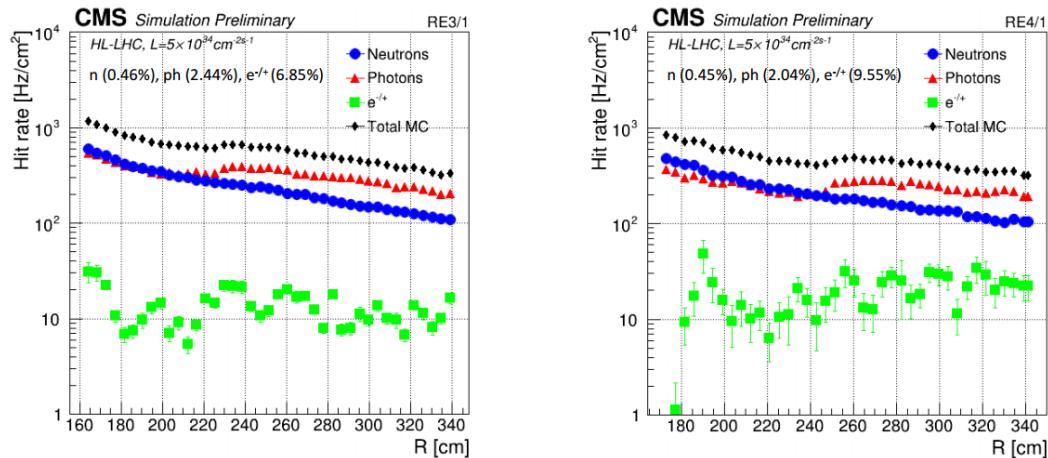

Figure 3.9: Expected hit rate due to neutrons, photons, electrons and positrons at HL-HLC instantaneous luminosity of $5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ in RE3/1 and RE4/1 chambers. The sensitivities of iRPCs used in the simulation for each particle are reported and differ from one endcap disk to another as the energies of the considered particles varies with the increasing distance from the interaction point.

Nevertheless, having only a single strip instead of pseudo-rapidity segmentation will increase the probability of double hits in the same channel. This probability was estimated to be low enough

as it shouldn't exceed 0.7%. This estimation was made assuming an average hit rate per unit area of 600 Hz/cm² in the iRPCs (see Figure 3.9), a cluster size (average number of strips fired per muon) of 2, a strip active area of 158.4 × 0.87 cm² and a safety factor 3 leading to an estimated rate per strip of 380 kHz corresponding to an average time interval of 2600 ns in between 2 consecutive hits. The time for a signal to go through the full strip length is about 10 ns to which can be added 1 ns of dead time and 2 TDC clock cycles of 2.5 ns for a minimal time interval of 16 ns necessary to avoid ambiguities. The probability of having ambiguous double hits in a strip is then the ratio in between this minimal time interval in between 2 consecutive hits and the average time interval estimated from the rate the detectors are subjected to.

The instantaneous luminosity at HL-LHC being very high, the rates at the level of the new chambers needed to be simulated in order to understand the necessary requirements for these detectors. The simulated results for different background components (neutrons, photons, electrons and positrons) are showed in Figure 3.9 assuming known sensitivities to these particles. It is showed that on average over the iRPC areas the rates would be of the order of 600 Hz/cm² (600 Hz/cm² seen in RE3/1 and 480 Hz/cm² in RE4/1) [27]. Thus, taking into account a safety factor of about 3, it was decided that improved RPCs should at least be certified for rates reaching 2 kHz/cm² which would be achieved thanks to several improvements on the design and on the electronics. The detectors design will be based on the existing RPC design as they will be double gaps. Similarly to the existing RPC system, the electrode material will be HPL although the thickness of the electrodes and of the gas gap will be reduced to 1.4 mm as a thinner gas gap leads to a decrease of deposited charge per avalanche as showed in Figure 3.10. The smaller the gas gap, the more the detector becomes sensitive to gap non-uniformities across the electrode planes making a gap of 1.4 mm a good compromise in between these two competing factors.

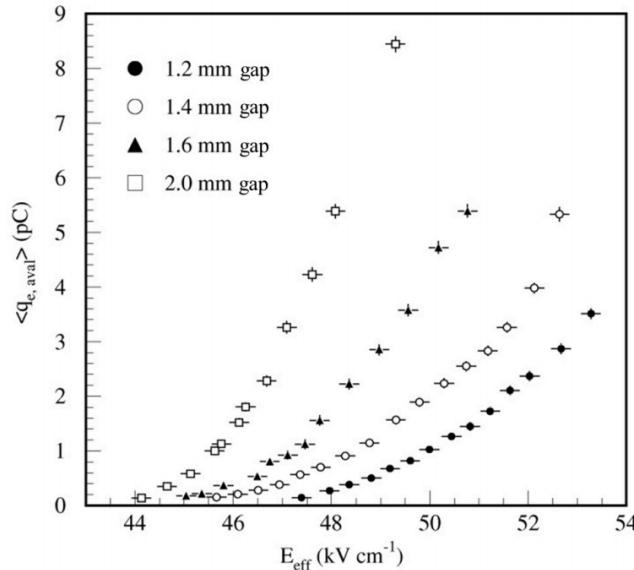

Figure 3.10: Measured average charge per avalanche as a function of the effective electric field for different gas gap thickness in double gap RPCs using HPL electrodes.

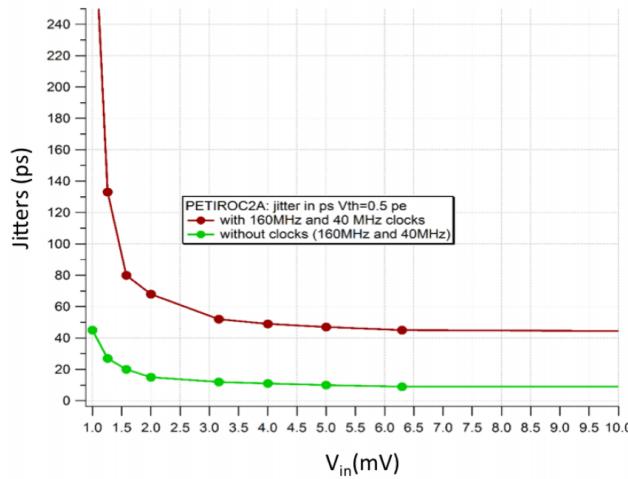

Figure 3.11: The PETIROC time jitter as a function of the input signal amplitude, measured with and without internal clocks.

1565 A lower charge deposition inside of the detector volume means a slower ageing and a longer life-
 1566 time for detectors subjected to high irradiation. But, in order to take advantage of the lower detector
 1567 gain, more sensitive electronics are required so that the part of gain that was formerly done in the gas
 1568 volume can be moved to the electronics. Achieving this with the technology developed more than
 1569 10 years ago for the present system is not possible as the signal over noise ratio of such electronics
 1570 doesn't allow to detect charges as low as 10 fC. Moreover, the new front-end electronics will need
 1571 to be radiation hard to survive to more than 10 years of HL-LHC conditions. The new technology
 1572 that has been chosen is based on the PETIROC ASIC manufactured by OMEGA and is a 64-channel
 1573 ASIC called CMS RPCROC on which the original SiGe technology will be replaced by CMOS to
 1574 increase its radiation hardness while keeping fast pre-amplification and discrimination with a very
 1575 low jitter that can reach less than 20 ps if no internal clock is used, as can be seen from Figure 3.11.
 1576 The ASIC is associated with an FPGA which purpose is to measure time thanks to a TDC with a
 1577 time resolution of 50-100 ps developed by Tsinghua University and that will provide a measurement
 1578 of the signal position along the strip with a precision of a few cm by measuring the signal timing
 1579 on both ends of the strips. In order to read-out all 96 strips, 3 ASICs and 3 TDCs, each having 64
 1580 channels, are hosted on a front-end board attached to the chamber.

1581

1582 [Wait for the analysis of 2018 GIF++ data to add interesting information about the time and
 1583 spatial resolution measured during test beam periods.]

1584

1585 3.3.2 Gas electron multipliers

1586 In the region closer to the interaction point where the spatial resolution is requested to be better
 1587 than 1 mm for the new detectors (at least for GE1/1 and ME0, GE2/1 being in the same order of
 1588 requested spatial resolution than the new iRPCs that will equip the third and fourth endcaps), the
 1589 choice has been made to use triple GEMs, micro pattern gaseous detectors, in the place of RPCs.
 1590 The GE1/1 project had been the first to be approved and demonstrators had been installed in CMS

already during LS1. The rest of the detectors will be installed during LS2 while the GE2/1 and ME0 projects are still under development. ME0, GE1/1 and GE2/1 will be installed respectively next to the HCAL endcap, on the first and on the second muon endcap disks as can be seen from Figure 3.3.

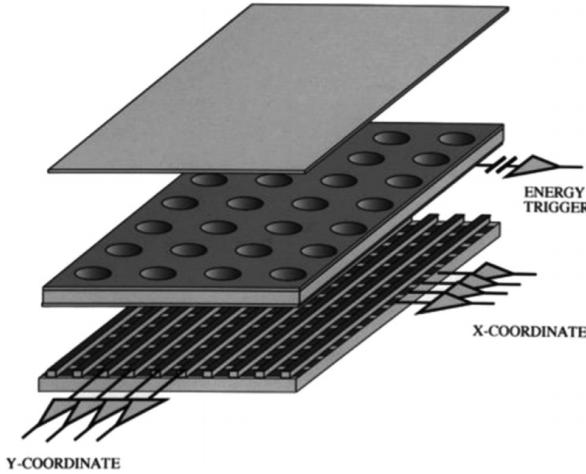

Figure 3.12: Schematics of a GEM showing the cathode on top, the GEM foil separating the gas volume into the drift region, in between the cathode and foil, and the induction region, in between the GEM foil and the anode, and the anode on which a 2D read-out is installed. A negative voltage is applied on the cathode while the anode is connected to the ground.

Gas Electron multipliers are gaseous detectors [28] which gas volume is confined in between 2 planar electrodes, the anode serving as read-out panel. The gas volume is divided in 2 or more regions by a single or multiple *GEM foils* as showed in Figure 3.12. These foils are very thin, of the order of a few tens of μm , and are pierced with holes as can be seen in Figure 3.13. Both surfaces of the GEM foils are clad with copper in order to apply a strong electric field in between each side that will generate very strong potentials in the holes. The gas region contained in between the cathode and the GEM foil is called the drift region as the electric field is not strong enough to cause avalanches and thus start an amplification. The primary electrons drift toward the foil and are accelerated and amplify by the very high potential within the holes, as showed in Figure 3.13. Then the electrons reach the second drift region in which they will induce signal on the read-out located on the anode. By restraining the amplification process at the level of the holes, the electrons can stay in a very confined space and thus induce a very localized current, providing the GEMs with a very good spatial resolution.

In order to achieve a stronger amplification, the amplification process can be repeated several times in a row. The GEMs that will be used in CMS are triple GEM detectors operated with a 70/30 gas mixture of Ar/CO_2 . They contain 3 GEM foils and thus 3 electron amplifications, as can be seen in Figure 3.14. The GEM foils used in CMS are 50 μm foils clad with 5 μm of copper on each side. The foils are pierced with double-canonical holes which inner and outer diameters are respectively 50 and 70 μm which are placed 140 μm from each other in an hexagonal pattern, as showed in Figure 3.13. These detectors have a time resolution better than 10 ns and reach very good spatial resolutions of less than 200 μrad as indeed the position of the hits is not measured along the strips but following the azimuthal angle granularity of the radially organized trapezoidal strips.

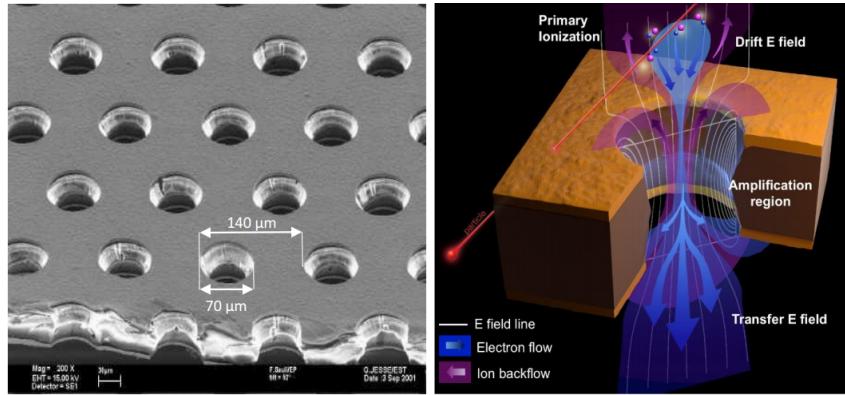

Figure 3.13: Left: Picture of a CMS GEM foil provided by a scanning electron microscope. Right: Representation of the electric field lines in a GEM hole and of the amplification that electrons and ions undergo in the hole's volume due to the very intense electric field.

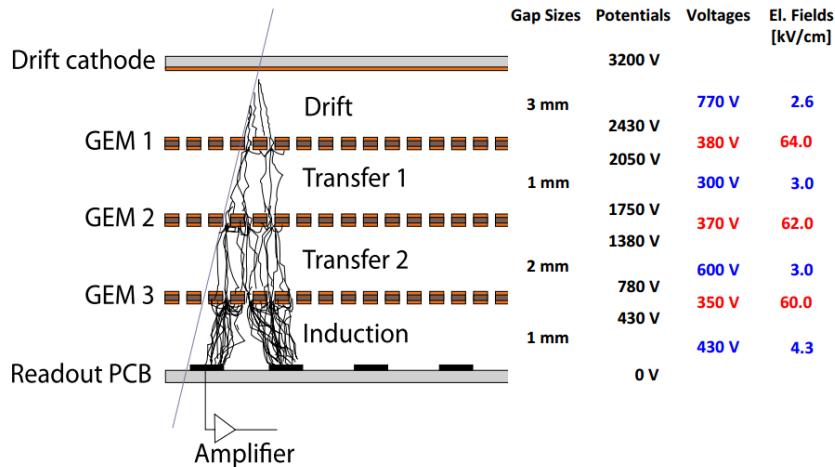

Figure 3.14: Schematic representation of CMS triple GEMs. The gas volume is divided into 4 areas. The drift area is the region where the primary electrons are created before being amplified a first time while passing through the first GEM foil. Then the process of drift and amplification is repeated twice in following two transfer areas and GEM foils. Finally, the charges have been amplified enough to induce current in the read-out strips while in the last drift area. The dimensions, potentials and electric fields are provided.

1616 The GEM Upgrade is divided into 3 subsystems as GE1/1 was the first approved project [29]
 1617 and that the detectors will already be installed during LS2. GE2/1 and ME0, on the other hand,
 1618 will profit of the R&D knowledge and skills developed for GE1/1 while the requirements for each
 1619 subsystem are different as they are not placed at the same distance from the interaction point. In this
 1620 very forward region, a different position with respect to the center of the detector can change dra-
 1621 matically the conditions in which the detectors will have to be operated. In terms of rate capability,
 1622 GE2/1, which is the furthest, is required to withstand 2.1 kHz/cm^2 while GE1/1 needs to be better
 1623 than 10 kHz/cm^2 and ME0, better than 150 kHz/cm^2 . In terms of ageing with respect to charge
 1624 deposition, ME0 needs to be certified to 840 mC/cm^2 , GE1/1 to 200 mC/cm^2 and GE2/1 only to

1625 9 mC/cm². All 3 detectors need to have a time resolution better than 10 ns and an angular resolution
 1626 better than 500 µrad.

1627 On each GE1/1 ring, 36 super chambers, consisting of 2 single GEM layers and spanning 10°,
 1628 will be installed covering the pseudo-rapidity region $1.6 < |\eta| < 2.2$ together with ME1/1 CSCs and
 1629 the reach of the muon system will be improved thanks to the GE2/1 that will overlap with the GE1/1
 1630 and cover a region from $|\eta| > 1.6$ to $|\eta| < 2.4$ and complete the redundancy of ME2/1. The super
 1631 chambers, built with 2 triple GEM layers each consisting of 4 single GEM modules due to the rather
 1632 large surface of the GE2/1 chambers, that will be installed on the first ring of the second endcap will
 1633 span 20° each, hence, a total of 72 chambers will be assembled to equip the muon system. Finally,
 1634 the ME0 installed near the HCAL endcap will cover the region $2.0 < |\eta| < 2.8$ and this subsystem
 1635 will consist in super modules of 6 layers of triple GEM detectors covering an azimuthal angle of 20°
 1636 leading to the construction of 216 single detectors.

1637 All these new GEM detectors will be using a similar internal layout which is described in Fig-
 1638 ure 3.14. The incoming muons will create detectable electron-ion pairs in the 3 mm thick drift
 1639 volume in which an electric field of 2.6 kV/cm is applied for the electrons to drift to the first GEM
 1640 foil on which a very intense field of 64 kV/cm is applied over a distance of only 60 µm which allows
 1641 for an average electronic gain of 20 to 25. After the first amplification stage, the electrons drift over
 1642 the 1 mm separating the 2 first GEM foils thanks to an electric field of 3.0 kV/cm and are again
 1643 amplified by a factor 20 to 25 while going through the second GEM foil to which is applied an elec-
 1644 tric field of 62 kV/cm. The electron drift another 2 mm towards the last GEM foil through a field
 1645 of 3.0 kV/cm and are multiplied one last time from a similar factor passing through the 60 kV/cm
 1646 of the last GEM foil holes. Finally, they drift along the 1 mm of the induction volume in a field of
 1647 4.3 kV/cm to reach the trapezoidal strips on the read-out PCB used as anode. The total detector
 1648 gain is approximately of the order of 10^4 and the resulting output signal is both due to the induction
 1649 of moving charges in the induction volume and of charge pic-up once they read the read-out strips.

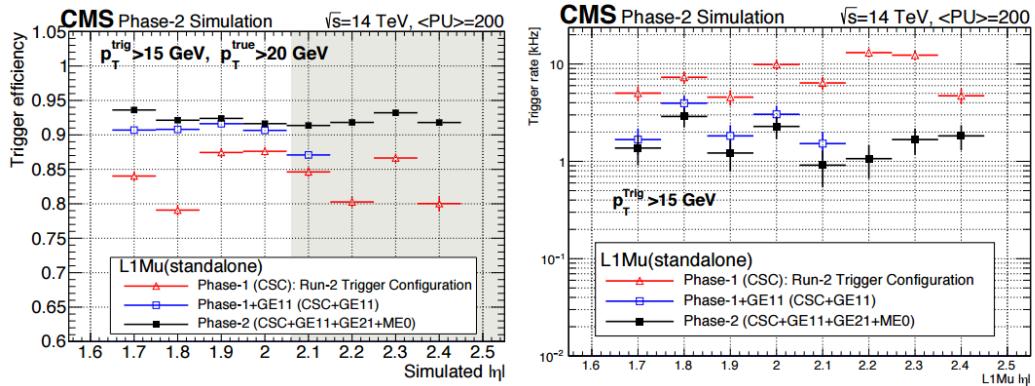

Figure 3.15: Simulated efficiency and rate of the standalone Level-1 muon trigger using tracks reconstructed in CSCs and all GEM stations compared with Phase-I values in the case where only CSCs are used or CSCs+GE1/1. The zones of inefficiency of the CSC subsystem are compensated by the addition of GEMs during Phase-II and the trigger rates is kept from increasing due to the high luminosity.

1650 Adding the GEMs into the forward region of the muon system will allow to strongly enhance
 1651 the Level-1 Trigger performance by reducing the inefficiency regions and the trigger rate as showed
 1652 in Figure 3.15. Moreover, benefiting from the good spatial and angular resolution of the GEMs, the

precision into the muon measurement will also be greatly improved by the addition of GEMs as can be seen from the simulation presented in Figure 3.16.

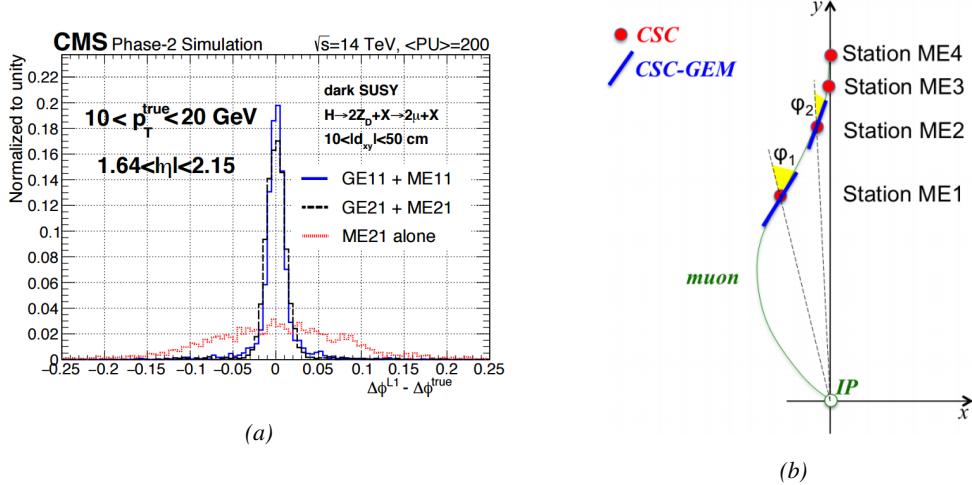

Figure 3.16: Figure 3.16a: Simulated resolution of the muon direction measurement $\Delta\phi$ with Phase-II conditions. In the second endcap station, the resolution is compared in the case of CSCs (ME2/I) alone and CSCs+GEMs (GE2/I+ME2/I) while a similar resolution measurement is given in the case of the first station (GE1/I+ME1/I). Figure 3.16b: The addition of GEM detectors on stations 1 and 2 (ME0 is considered to contribute to station station 1) as redundant system to CSCs allows to improve the muon momentum improvement through a more accurate measurement of the local bending angles ϕ_1 and ϕ_2 .

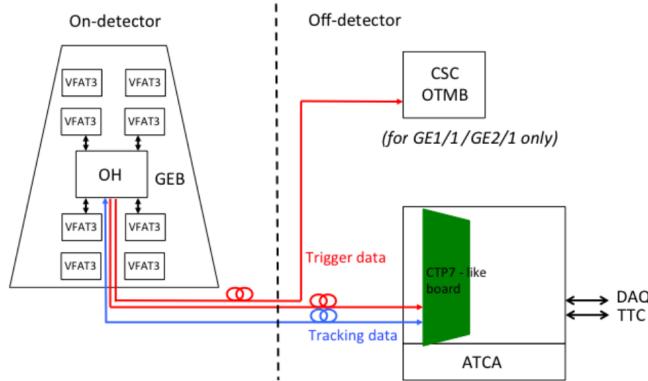

Figure 3.17: Schematics of the data communication chain for DAQ of the GEM subsystems. The sending of trigger data via optical links to the CSC OTMBs is only done for GE1/I and GE2/I to match the data with ME1/I and ME2/I.

The read-out of GEMs will use the same technology. The anode planes used as read-out PCBs and referred to as GEM Electronics board (GEB) host on their outer surface VFAT3 ASICs that connect to a total of 128 strips for a very fine angular granularity. Along the endcap radius, the strips are divided into 8 pseudo-rapidity partitions. In the case of GE1/1 and ME0, each η -partition consist in 384 read-out strips connected into 3 VFAT3 ASICs and offering a while the large GE2/1 partitions

1660 contain twice as many channels. Both GE1/1 and GE2/1 strips have an angular pitch of $474\text{ }\mu\text{m}$
 1661 while this of ME0 is twice larger due to its proximity with the interaction point. The VFAT3 ASICs
 1662 allow for a latency better than the $12.5\text{ }\mu\text{s}$ required by CMS Level-1 Trigger and there frequencies
 1663 goes up to 1 MHz. They are connected into the Optohybrid Board (OH) and this full ensemble
 1664 (GEB+VAT3+OH) constitute the on-chamber electronics. The OH is then sending the data to the
 1665 modules constituting the DAQ of the GEM system via optical fibers. These back-end electronics
 1666 modules are located in the service cavern of CMS and host CMS communication devices, used to
 1667 have a common clock, and control and links to the Endcap Muon Track Finder (EMTF) system.
 1668 Moreover, GE1/1 and GE2/1 also have links with the CSC OTMBs as the OH of these 2 subsystems
 1669 send data into these boards. This communication chain can be seen in Figure 3.17.

1670

1671 The detectors that will placed in CMS will have to live through Phase-II without significant
 1672 performance degradation to ensure an efficient data taking and the possibility to investigate more
 1673 exotic physics. As the 3 GEM subsystems will be using the same detector technology, the choice
 1674 was made to certify the GEMs in the worst of the 3 environments, i.e. the ME0 station located right
 1675 behind the HCAL. According to FLUKA simulation, including all the latest foreseen upgrades into
 1676 the CMS detector geometry, it was shown that the maximal hit rate expected in ME0 would be of
 1677 the order of 50 kHz/cm^2 with contributions of neutrons (6 kHz/cm^2), photons (35 kHz/cm^2), and
 1678 electrons and positrons (8 kHz/cm^2) resulting in a charge deposition a little lower than 300 mC/cm^2
 1679 after 10 years of HL-LHC [23]. It is necessary to understand the classical ageing effects on the GEMs
 1680 but also premature ageing due to contaminants in the gas mixture leading to polymerization on the
 1681 surface of the GEM foils during operation and the effect of discharges on the detector operations if
 1682 they have to happen during their lifetime.

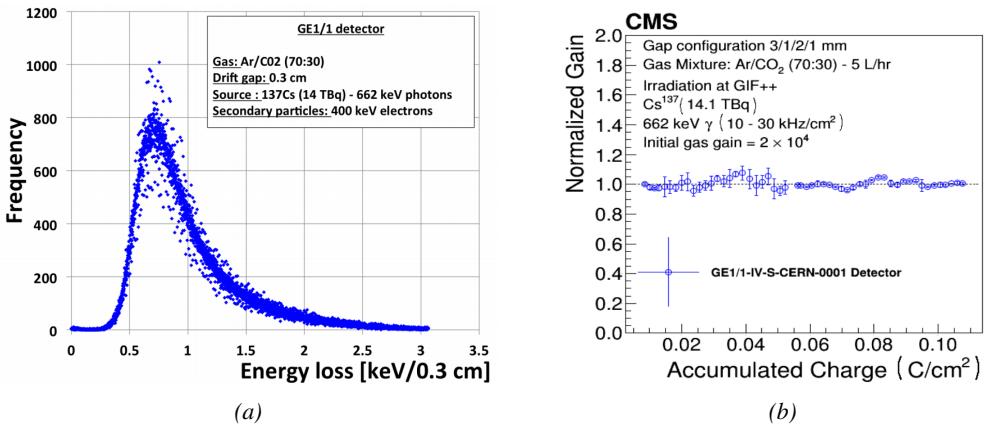

Figure 3.18: Figure 3.18a: Energy spectrum of GIF++ ^{137}Cs source as measured by the GE1/1 detector installed in GIF++. Figure 3.18b: Evolution of the normalized gain of the GE1/1 detector installed at in GIF++ as a function of the integrated charge per unit area. The first part of the study, up to a charge of 55 mC/cm^2 had been done in the former Gamma Irradiation Facility (GIF) that has now been dismantled following the construction of GIF++. No variation of the normalized gain can be observed after an accumulation of 110 mC/cm^2 .

1683

To characterize the classical ageing effects, a campaign is being conducted in the new Gamma Irradiation Facility (GIF++) of CERN where a GE1/1 detector operated at its nominal gain is placed 50 cm from the facility's 14 TBq ^{137}Cs source which emits gammas at an energy of 662 keV. In

order to spot any ageing of the detector, the effective gain is kept monitored, as can be seen in Figure 3.18b, as its variations gives clues about different aspects of the detector such as the geometry of the holes, the electric field configuration or the gas composition. The monitoring of the gamma energy distribution, showed on Figure 3.18a, can give an idea on the evolution of the performance of the chamber and finally, the evolution of the currents through time also is a good indicator of the appearance of dark current in the detector that would be due to the emission of electrons by thin insulating layers of the detector subjected to a long lasting irradiation known as Malter effect. At the time the Technical Design Report (TDR) for the Phase-II upgrade of the muon system was written [23], the GEM group had reported a total integrated charge of 110 mC/cm^2 which, if compared with 10 years of HL-LHC operation, represents a safety factor of 18 for the GE1/1 subsystem and a factor 37 for the GE2/1 subsystem but only 39% of the total expected ME0 integrated charge. It is estimated that reaching the total integrated charge necessary to certify the detectors for Phase-II operation will take another 2 to 3 years. Nevertheless, the present status of the longevity study shows no degradation of the performance of the detector installed in GIF++ as can be seen through Figure 3.18.

Aside of the classical ageing tests, outgassing of the different materials composing the GEMs have been conducted by placing the different materials to be tested into an outgassing box that consists in a stainless steel cylinder through which the CMS GEM 70/30 gas mixture of Ar/CO_2 with the possible contaminants is flowed while the detector is exposed to the continuous irradiation of a radioactive source and the heat is raised to enhance the outgassing. From the detector that was placed into this outgassing box, only one component was identified to cause loss of performance due to outgassing. This component was the polyurethane *Cell-Pack* used to coat the internal frame of the GEMs and the polymerization on its surface caused a 20% decrease of the gas gain. this polyurethane was replaced with a new one for which no outgassing effect causing a loss of performance was reported.

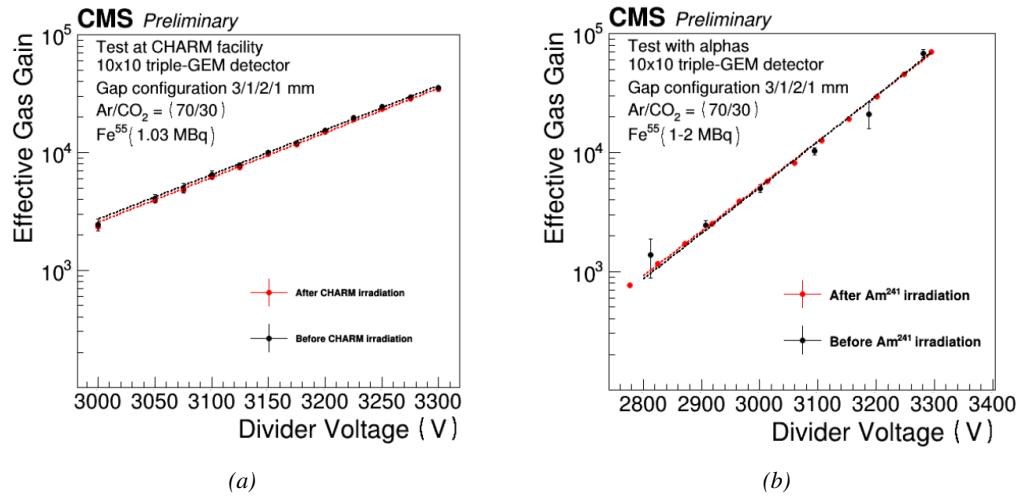

Figure 3.19: Figure 3.19a: Comparison of the gas gain as a function of the divider voltage before and after the irradiation of a triple-GEM by neutrons in CHARM. Figure 3.19b: Comparison of the gas gain as a function of the divider voltage before and after the irradiation of a triple-GEM by alpha particles.

Finally, even though the triple-GEM technology makes the detectors safe of discharges thanks to

its several amplification stages that allow to reach high gas gain using a relatively low electric field applied on the foils and to the distance separating the last foil from the read-out panel that is high enough to prevent discharging from developing all the way to the read-out, and hence, be stopped before it can cause any harm, it is important to have a good understanding of the discharge probability to ensure a safe operation over long periods. In order to further prevent discharges to develop in the detector volume, the GEM foils' power supply have been sectorized and protection resistors have been installed to limit the energy available for the discharge development. To reproduce the high-energy neutron background conditions of CMS, a GE1/1 detector have been placed in the CHARM facility of CERN. This facility allows to irradiate the detectors with a neutron fluence as high as $2.5 \times 10^8 / \text{cm}^2$. The detectors were operated with a slightly higher gain of 3.5×10^4 . It was measured that the discharge probability for a GEM operated under CMS conditions was of 2.85×10^{-9} per heavily ionizing particle with a 95% confidence level that would correspond to 225 discharges per cm^2 in ME0, 17 in GE1/1 and 12 in GE2/1 during the full HL-LHC period. According to Figure 3.19a, no degradation of the performance was observed after the irradiation at CHARM were 24 discharges per unit area were reported. Nevertheless, another test were the detector was exposed to a 5.5 MeV alpha source and were 450 discharges per unit area were reported didn't show any drop of performances either, as can be seen in Figure 3.19b.

3.3.3 Installation schedule

The previous discussion on the different upgrade projects makes it clear that a lot of work is scheduled for CMS to be ready at the end of LS3 for HL-LHC. Conducting all the upgrades of the muon system together with upgrades of the other subsystems like the replacement of the Tracker and of part of the ECAL, will prove to be very difficult as the opening of CMS to access the Barrel will be done by fully opening the endcaps leaving only the first disk to be accessible. Thus, most subsystems have planned early installation over LS2, and the following YETS until LS3 in order to give more space to LS3 schedule.

First of all, LS2 will see the installation of GE1/1 detectors, all the on-detector schedule of CSCs and the installation of the necessary services for the improved RPCs to be installed later, such as the HV and LV power supply lines, the gas and cooling lines or signal cables. CSCs will have a huge work to do during LS2 as they will need to extract all of their detectors to refurbish them with upgraded DCFEB and ALCT mezzanine boards. The GE1/1 services were installed during LS1 together with a few demonstrator and only the detectors needs to be integrated into the first endcap disk. The detectors are presently being built and tested at the different assembly site to prepare for a smooth LS2 work.

The work of GEMs will be continued during the following YETS during which is planned the installation of the GE2/1 stations to only leave the ME0 to be installed during LS3. The iRPC program will follow a similar path as the new detectors will be installed during the YETS preceding LS3 in preparation of the fact that the endcap disks will not be accessible during LS3. This way, all the subsystems, but DTs, made great effort on planning their installation and integration within CMS only to have to deal with off-detector issues during the LS3 period, such as the replacement of ODMBs and HV system in the case of CSCs or the upgrade of the RPC Link System. Finally, during LS3 are scheduled the replacement of DT minicrates electronics and the installation and integration of ME0 GEMs together with the HGCAL.

1755 3.4 Implications of the different upgrades on the Level-1 Trigger. 1756 Improvement of physics performance.

1757 The upgrades of the different subsystems will have a subsequent impact on the Level-1 Trigger.
 1758 Indeed, although its main scheme will not be affected, the efficiency of the trigger in identifying muons and provide the DAQ with good and fast trigger that can cope with HL-LHC
 1759 instantaneous luminosity is a major improvement. In addition to the upgrade of the muon system in
 1760 terms of trigger accept rate and latency, the Level-1 Trigger will get extra information in including
 1761 the Tracker Trigger into its Muon Track Finder logic and combine the L1 Muon Trigger with Tracker
 1762 and Calorimeter Triggers to generate a Global L1 Trigger with a much better momentum resolution,
 1763 as showed in Figure 3.20.

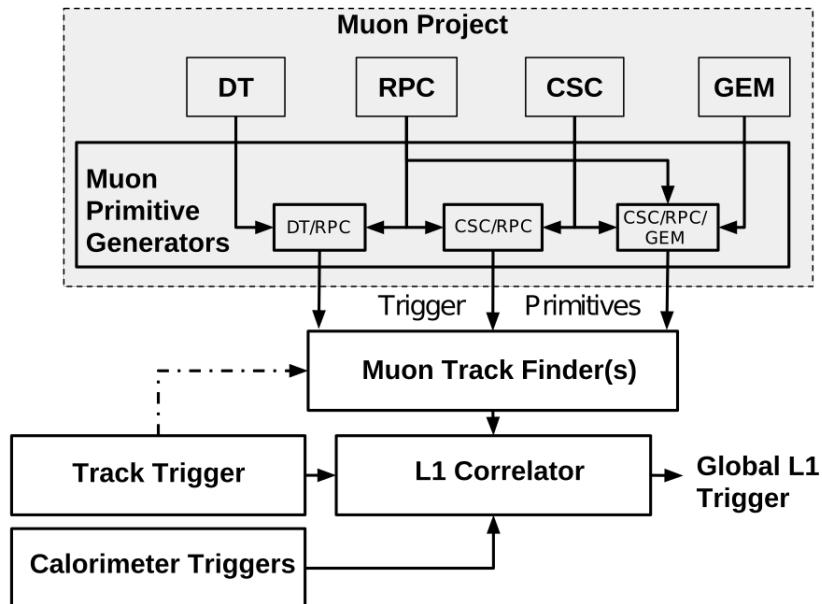

Figure 3.20: Data flow of the Level-1 Trigger during Phase-II operations.

1765 In terms of muon trigger, 3 regions are considered due to their different track finding logic: the
 1766 Barrel Muon Track Finder (BMTF), the Endcap Muon Track Finder (EMTF) for both the barrel and
 1767 endcap regions, and finally the Overlap Muon Track Finder (OMTF) which concerns the pseudo-
 1768 rapidity region in which there is a common coverage by both the barrel and endcap muon systems.
 1769 This region can be seen in Figure 3.3 for $0.9 < |\eta| < 1.2$ and requires a specific more complex
 1770 logic to provide with an efficient reconstruction of the muons due to the different orientation of
 1771 the detectors and of the more complex magnetic field of this region that needs to be taken into
 1772 account. The benefits of the upgrade for each of these track finders will be coming from different
 1773 improvements and will be detailed sector by sector.

3.4.1 Barrel region

The main contribution to the improvement of the BMTF is the time resolution improvement of RPC link systems that will allow to take profit of the full 1.5 ns resolution of the detectors. The upgrade of DT electronics is also to take into account as the trigger primitive generator will be renewed through the use of TDCs that will send the digitized signals directly to the back-end electronics instead of having an on-detector trigger logic as it will be the case until the end of Phase-I. The front data of both DTs and RPCs will be sent to the same back-end electronics. These upgrades were detailed in section 3.2 and will lead to a more robust operation of the trigger in the barrel region. Indeed, the combination of RPC hits in addition to the DT primitives will improve the bunch crossing assignment and improve the efficiency of the trigger in between the wheels where the quality of DT primitives is the poorest. Moreover, having a redundant information is important in the case of failure of one of either subsystems.

1792

Physics of Resistive plate chambers

1793 A Resistive Plate Chamber (RPC) is a gaseous detector using the same physical processes described
1794 in Chapter 3. It has been developed in 1981 by Santonico and Cardarelli [30], under the name of
1795 *Resistive Plate Counter*, as an alternative to the local-discharge spark counters proposed in 1978
1796 by Pestov and Fedotovich [31, 32]. Working with spark chambers implied using high-pressure gas
1797 and high mechanical precision which the RPC simplified by formerly using a gas mixture of argon
1798 and butane flowed at atmospheric pressure and a constant and uniform electric field propagated
1799 in between two parallel electrode plates. Moreover, a significant increase in rate capability was
1800 introduced by the use of electrode plate material with high bulk resistivity, preventing the discharge
1801 from growing throughout the whole gas gap. Indeed, the effect of using resistive electrodes is that
1802 the constant electric field is locally canceled out by the development of the discharge, limiting its
1803 growth.

1804 Through its development history, different operating modes [33–35] and new detector designs [36–
1805 38] have been discovered, leading to further improvement of the rate capability of such a detector.
1806 Moreover, the addition of SF_6 into the gas mix improved the stability of operation of the RPC [39,
1807 40].

1808 The low developing costs and easily achievable large detection areas offered by RPCs, as well as
1809 the wide range of possible designs, made them a natural choice to as muon chambers and/or trigger
1810 detectors in multipurpose experiments such as CMS [21] or ATLAS [41], time-of-flight detectors in
1811 ALICE [42], calorimeter with CALICE [43] or even detectors for volcanic muography with ToMu-
1812 Vol [44].

1813 4.1 Principle

1814 RPCs are ionisation detectors composed of two parallel resistive plate electrodes in between which
1815 a constant electric field is set. The space in between the electrodes, referred as *gap*, is filled with a
1816 dense gas that is used to generate primary ionization into the gas volume. The free charge carriers
1817 (electrons and cations) created by the ionization of the gas molecules are then accelerated towards

¹⁸¹⁸ the electrodes by the electric field, as shown in Figure 4.1 [45].

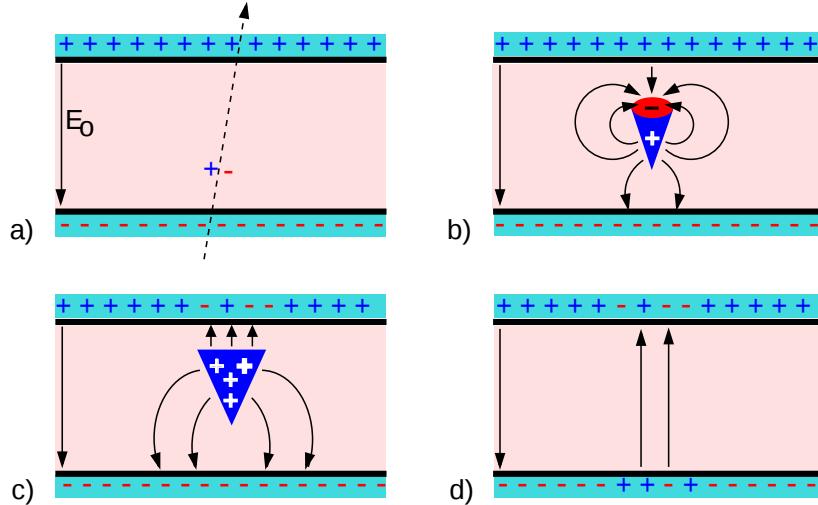

Figure 4.1: Different phases of the avalanche development in the RPC gas volume subjected to a constant electric field E_0 . a) An avalanche is initiated by the primary ionisation caused by the passage of a charged particle through the gas volume. b) Due to its growing size, the avalanche starts to locally influence the electric field. c) The electrons, lighter than the cations reach the anode first. d) The ions reach the cathode. While the charges have not recombined, the electric field in the small region around the avalanche stays affected and locally blind the detector.

¹⁸¹⁹ RPCs being passive detectors, a current on pick-up copper read-out placed outside of the gas
¹⁸²⁰ volume is induced by the charge accumulation during the growth of the avalanche. As a result,
¹⁸²¹ the time resolution of the detector is substantially increased as the output signal is generated while
¹⁸²² the electrons are still in movement. The advantage of a constant electric field, over multi-wire
¹⁸²³ proportional chambers, is that the electrons are being fully accelerated from the moment charge
¹⁸²⁴ carriers are freed and feel the full strength of the electric field that doesn't depend on the distance to
¹⁸²⁵ the readout and that the output signal doesn't need for the electrons to be physically collected.

¹⁸²⁶ The typical gas mixture RPCs are operated with is generally composed of 3 gas compounds.

- ¹⁸²⁷ • Tetrafluoroethane ($C_2F_4H_2$), also referred to as *Freon*, is the principal compound of the RPC
¹⁸²⁸ gas mixtures, with a typical fraction above 90%. It is used for it's high effective Townsend
¹⁸²⁹ coefficient and the great average fast charge that allows to operate the detector with a high
¹⁸³⁰ threshold with respect to argon, for example, that has similar effective Townsend coefficient
¹⁸³¹ but suffers from a lower fast charge. To operate with similar conditions, argon would require a
¹⁸³² higher electric field leading to a higher fraction of streamers, thus limiting the rate capability
¹⁸³³ of the detector [46].
- ¹⁸³⁴ • Isobutane (i- C_4H_{10}), only present in a few percent in the gas mixtures, is used for its UV
¹⁸³⁵ quenching properties [47] helping to prevent streamers due to UV photon emission during the
¹⁸³⁶ avalanche growth.
- ¹⁸³⁷ • Sulfur hexafluoride, (SF_6), referred to simply as *SF6*, is used in very little quantities for its
¹⁸³⁸ high electronegativity. Excess of electrons are being absorbed by the compound and streamers

1839 are suppressed [40]. Nevertheless, a fraction of SF_6 higher than 1% will not bring any extra
 1840 benefit in terms of streamer cancelation power but will lead to higher operating voltage [39],
 1841 as can be understood through Figure 4.2.

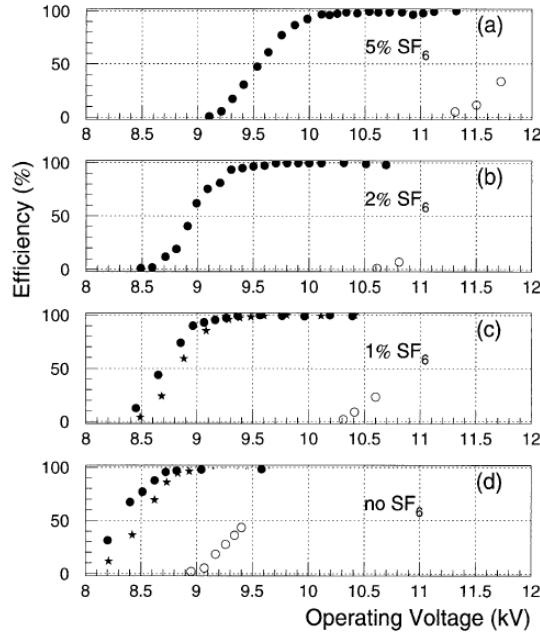

Figure 4.2: Effeciency (circles and stars with 30 mV and 100 mV thresholds respectively) and streamer probability (opened circles) as function of the operating voltatge of a 2 mm single gap HPL RPC flushed with a gas mixture containing (a) 5%, (b) 2%, (c) 1% and (d) no SF_6 [39].

1842 After an avalanche developed in the gas, a time long compared to the development of a discharge
 1843 is needed to recombine the charge carriers in the electrode material due to their resistivity. This
 1844 property has the advantage of affecting the local electric field and avoiding sparks in the detector
 1845 but, on the other hand, the rate capability is intrinsically limited by the time constant τ_{RPC} of the
 1846 detector. Using a quasi-static approximation of Maxwell's equations for weakly conducting media,
 1847 it can be shown that the time constant τ_{RPC} necessary to the charge recombination at the interface
 1848 in between the electrode and the gas volume is given by the Formula 4.1 [48].

$$\tau_{RPC} = \frac{\epsilon_{electrode} + \epsilon_{gas}}{\sigma_{electrode} + \sigma_{gas}} \quad (4.1)$$

1849 A gas can be assimilated to vacuum, leading to $\epsilon_{gas} = \epsilon_0$ and $\sigma_{gas} = 0$, and the electrodes
 1850 permittivity and conductivity can be written as $\epsilon_{electrode} = \epsilon_r \epsilon_0$ and $\sigma_{electrode} = 1/\rho_{electrode}$,
 1851 showing the strong dependence of the time constant to the electrodes resistivity in Formula 4.2.

$$\tau_{RPC} = (\epsilon_r + 1)\epsilon_0 \times \rho_{electrode} \quad (4.2)$$

1852 Very few materials with a low enough resistivity exist in nature. The resistivity targeted to build
 1853 RPCs ranges from 10^9 to $10^{12} \Omega \cdot \text{cm}$. The most common RPC electrode materials are displayed in
 1854 Table 4.1. When the doped glass and ceramics can offer short time constants of the order of 1 ms,

¹⁸⁵⁵ the developing cost of such materials is quite high due to the very low demand. Thus, High-pressure
¹⁸⁵⁶ laminate (HPL) is often the choice for high rate experiments using very large RPC detection areas.
¹⁸⁵⁷ Other experiments working at cosmic muon fluxes can safely operate with ordinary float glass.

Material	$\rho_{electrode}$ ($\Omega \cdot \text{cm}$)	ϵ_r	τ_{RPC} (ms)
Float glass	10^{12}	~ 7	~ 700
High-pressure laminate	10^{10} to 10^{12}	~ 6	~ 6 to 600
Doped glass (LR S)	10^9 to 10^{11}	~ 10	~ 1 to 100
Doped ceramics (SiN/SiC)	10^9	~ 8.5	~ 1
Doped ceramics (Ferrite)	10^8 to 10^{12}	~ 20	~ 0.2 to 2000

Table 4.1: Properties of the most used electrode materials for RPCs.

¹⁸⁵⁸ 4.1.1 Electron drift velocity

¹⁸⁵⁹ Talk about the electron drift velocity and mention the time resolution of RPCs.

¹⁸⁶⁰ 4.2 Rate capability and time resolution of Resistive Plate Chambers

¹⁸⁶² As already previously discussed, the electrode material plays a key role in the max intrinsic rate
¹⁸⁶³ capability of RPCs. R&D is being done to develop at always cheaper costs material with lower
¹⁸⁶⁴ resistivity. Nevertheless, the amount of charge released, i.e. the size of the discharge, if reduced
¹⁸⁶⁵ leads to a smaller blind area in the detector, increasing the rate capability of the detector.

¹⁸⁶⁶ 4.2.1 Operation modes

¹⁸⁶⁷ RPCs where developed early 1980s. At that time it was using an operating mode now referred to
¹⁸⁶⁸ as *streamer mode*. Streamers are large discharges that develop in between the 2 electrodes enough
¹⁸⁶⁹ to locally discharge the electrodes. If the electric field inside of the gas volume is strong enough,
¹⁸⁷⁰ with electrons being fast compared to ions, a large and dense cloud of positive ions will develop
¹⁸⁷¹ nearby the anode and extend toward the cathode while the electrons are being collected, eventually
¹⁸⁷² leading to a streamer discharge due to the increase of field seen at the cathode. the field is then strong
¹⁸⁷³ enough so that electrons are pulled out of the cathode. Electrodes, though they are a unique volume
¹⁸⁷⁴ of resistive material, can be assimilated to capacitors. At the moment an electric field is applied in
¹⁸⁷⁵ between their outer surfaces, the charge carriers inside of the volume will start moving leading to
¹⁸⁷⁶ a situation where there is no voltage across the electrodes and a higher density of negative charges,
¹⁸⁷⁷ i.e. electrons, on the inner surface of the cathode. Finally, when a streamer discharge occurs, these
¹⁸⁷⁸ electrons are partially released in the gas volume contributing to increase the discharge strength until
¹⁸⁷⁹ the formation of a conductive plasma, the streamer. This can be understood through Figure 4.3 [33].
¹⁸⁸⁰ Streamer signals are very convenient in terms of read-out as no amplification is required with output
¹⁸⁸¹ pulses amplitudes of the order of a few tens to few hundreds of mV as can be seen on Figure 4.4.

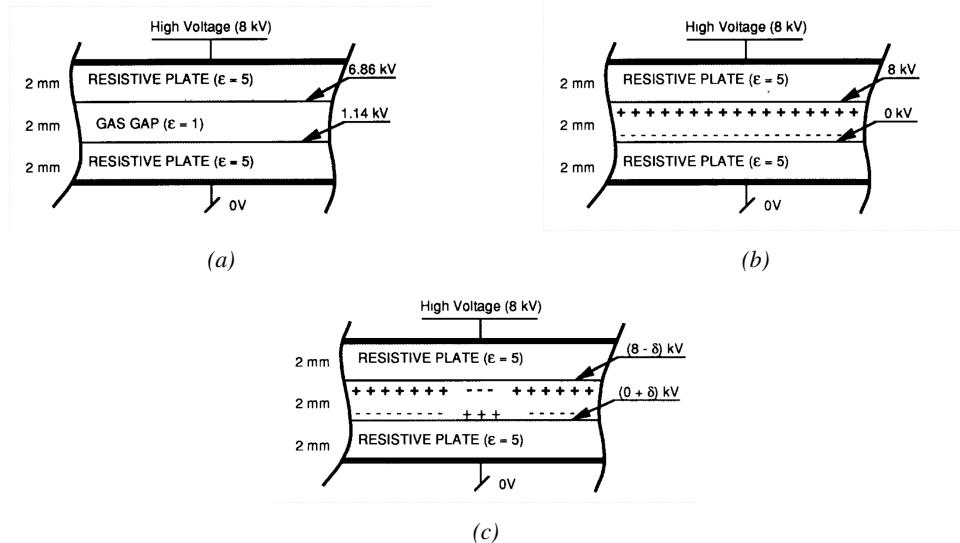

Figure 4.3: Movement of the charge carriers in an RPC. Figure 4.3a: Voltage across an RPC whose electrode have a relative permittivity of 5 at the moment the tension s applied. Figure 4.3b: After the charge carriers moved, the electrodes are charged and there is no voltage drop over the electrodes anymore. The full potential is applied on the gas gap only. Figure 4.3c: The streamer discharge initiated by a charged particle transports electrons and cations towards the anode and cathode respectively.

When the electric field is reduced though, the electronic gain is small until the electrons get close enough to the anode and the positive ion cloud is much smaller. The electric field cannot rise to the point a field emission of electrons on the cathode is possible. The resulting signal is weak, of the order of a few mv as shown on Figure 4.4, and requires amplification. This is the *avalanche mode* of RPC operation.

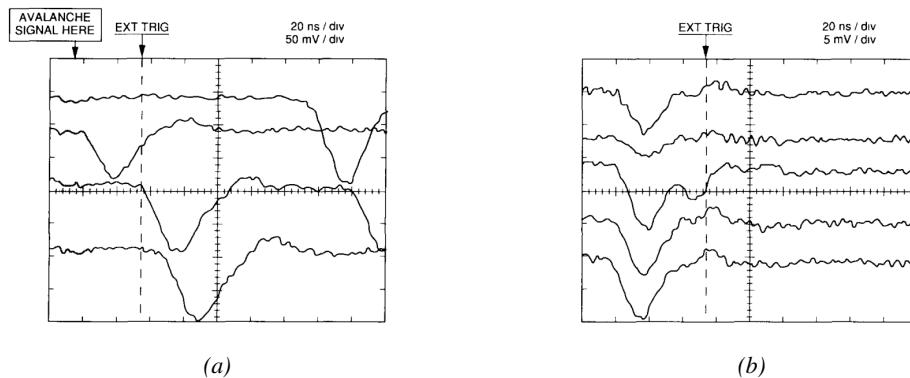

Figure 4.4: Typical oscilloscope pulses in streamer mode (Figure 4.4a) and avalanche mode (Figure 4.4b). In the case of streamer mode, the very small avalanche signal is visible.

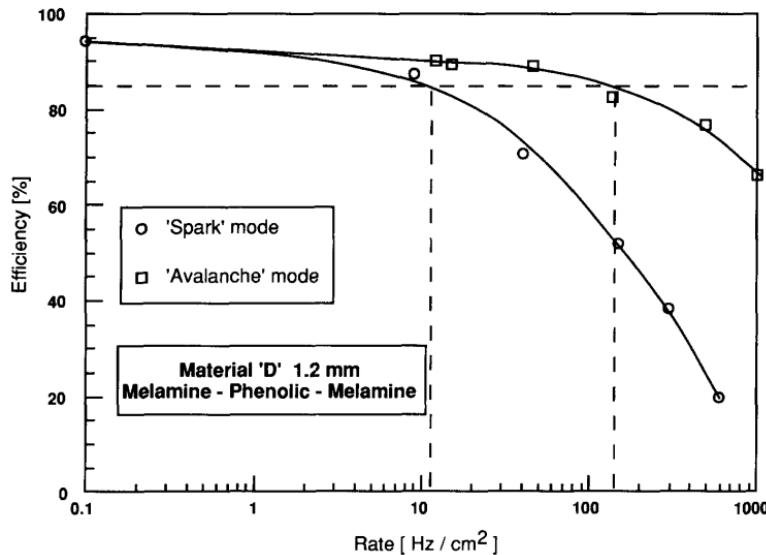

Figure 4.5: Rate capability comparison for the streamer and avalanche mode of operation. An order of magnitude in rate capability for a maximal efficiency drop of 10% is gained by using the avalanche mode over the streamer mode.

This mode offers a higher rate capability by providing smaller discharges that don't affect the electrodes charge and are more locally contained in the gas volume as was demonstrated by Crotty with Figure 4.5 [33]. The detector only stays locally blind the time the charge carriers are recombined and there is no need for electrode recharge which is a long process affecting a large portion of the detector. Another advantage of avalanche signals over streamer is the great time consistency. Figure 4.4 shows very clearly that avalanche signals have a very small time jitter. This is a natural choice for high rate experiments.

4.2.2 Detector designs and performance

Different RPC design have been used and each of them present its own advantages. Historically, the first type of RPC to have been developed is what is referred now to *narrow gap* RPC [30, 49]. After the avalanche mode has been discovered [33], it has been proven that increasing the width of the gas gap lead to higher rate capability, due to lower charge deposition per avalanche, and lower power dissipation [49]. Nevertheless, by increasing the gas gap width, the time resolution of the detector decreases. This is a natural result if the increase of active gas volume in the detector is taken into account. Indeed, for a given threshold, only the small fraction of gas closest to the cathode will provide enough gain to have a detectable signal. In the case of a wider gas volume, the active region is then larger and a larger time jitter is introduced with the variation of starting position of the avalanche, as discussed in [36]. To solve improve both the time resolution and the rate capability, different methods were used trying to get advantages of both narrow and wide gap RPCs.

1906 **4.2.2.1 Double-gap RPC**

1907 Double-gap RPCs are made out of 2 narrow RPC detectors. The 2 RPC gaps are stacked on top of
 1908 each other as shown in Figure 4.6. This detector layout, popularized by the two multipurpose experiments
 1909 CMS [21] and ATLAS [41] at LHC, can be used as an OR system in which each individual
 1910 chamber participates in the output signal. The gain of such a detector is greatly reduced with respect
 1911 to single-gap RPCs with an efficiency plateau reached at lower voltage, as visible on Figure 4.7.

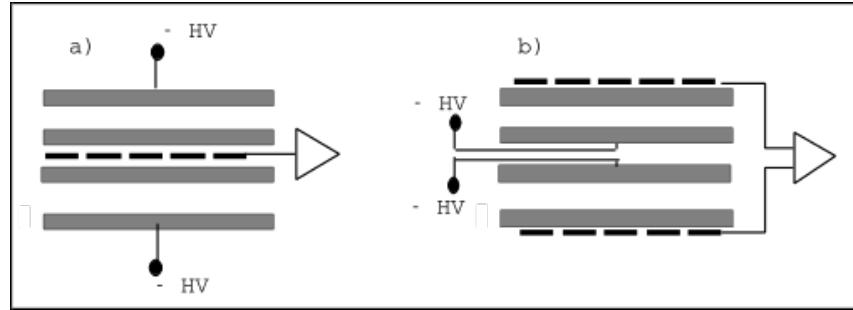

Figure 4.6: Possible double-gap RPC layouts: a) "standard" 1D double-gap RPC, as used in CMS experiment, where the anodes are facing each other and a 1D read-out plane is sandwiched in between them, b) double read-out double-gap RPC as used in ATLAS experiment, where the cathodes are facing each other and 2 read-out planes are used on the outer surfaces. This last layout can offer the possibility to use a 2D reconstruction by using orthogonal read-out planes.

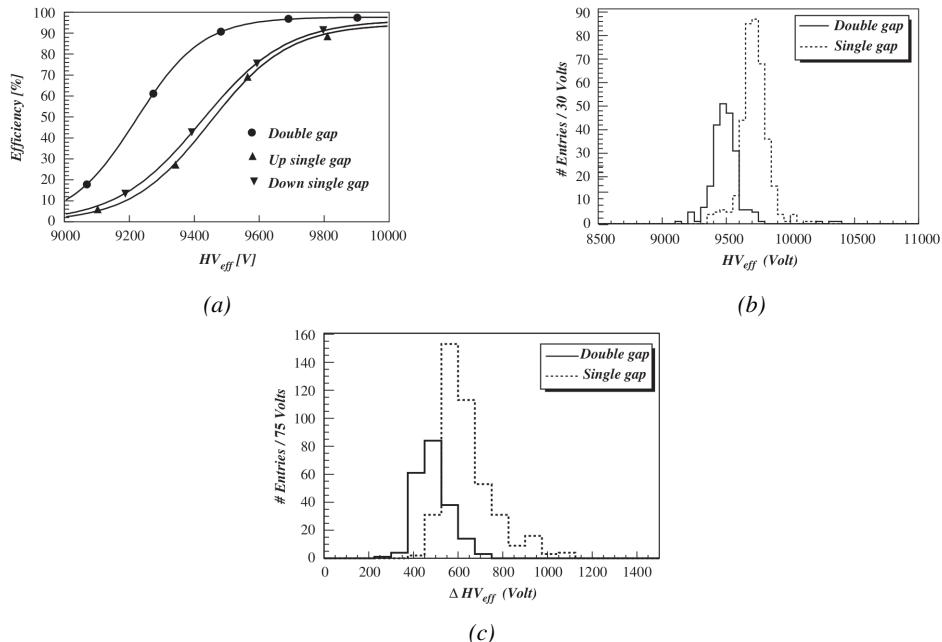

Figure 4.7: Comparison of performance of CMS double and single gap RPCs using cosmic muons [50]. Figure 4.7a: Comparison of efficiency sigmoids. Figure 4.7b: Voltage distribution at 95% of maximum efficiency. Figure 4.7c: $\Delta_{10\%}^{90\%}$ distribution.

4.2.2.2 Multigap RPC (MRPC)

MRPCs are layouts in which floating sub electrode plates are placed into a wide gap RPC to divide the gas volume and create a sum of narrow gaps [36, 37]. The time resolution of such a detector can reach of few tens of ps, with gas gaps of the order of a few hundred μm as shown in Figure 4.8 representing ALICE Time-of-flight (ToF) MRPCs.

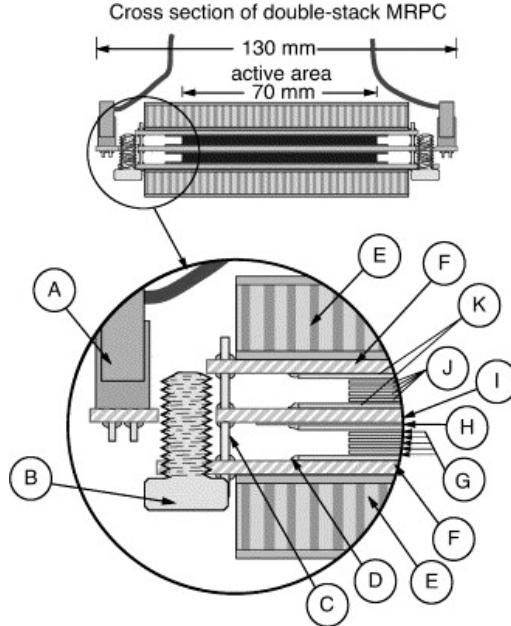

Figure 4.8: Presentation of ALICE MRPC using $250 \mu\text{m}$ gas gaps, $620 \mu\text{m}$ outer glass electrodes and $550 \mu\text{m}$ inner floating electrodes. More details on the labels are given in [51].

Sometimes used as a double multigap RPC, taking advantage of the OR of double gap RPCs, the MRPC is mainly used as ToF detector [51–55] due to its excellent timing properties that allow to perform particle identification as explained by Williams in [56]. The principle of particle identification using ToF is simply the measurement of the velocity of a particle. Indeed, particles are defined by their mass (for the parameter of interest here, their electric charge being measured using the bending angle of the particles traveling through a magnetic field) and this mass can be calculated by measuring the velocity β and momentum of the particle:

$$\beta = \frac{p}{\sqrt{p^2 + m^2}} \quad (4.3)$$

Intuitively, it is trivial to understand that 2 different particles having the same momentum will have a different velocity due to the mass difference and thus a different flight time T_1 and T_2 through the detector and this is used to separate and identify particles. The better the time resolution of the ToF system used, the stronger will the separation be:

$$T = \frac{L}{v} = \frac{L}{c \cdot \beta}, \quad \Delta T = T_1 - T_2 = \frac{L}{c} \left(\sqrt{1 + m_1^2/p^2} - \sqrt{1 + m_2^2/p^2} \right) \cong (m_1^2 - m_2^2) \frac{L}{2cp^2} \quad (4.4)$$

¹⁹²⁸ An example of particle identification is given for the case of STAR experiment in Figure 4.9.

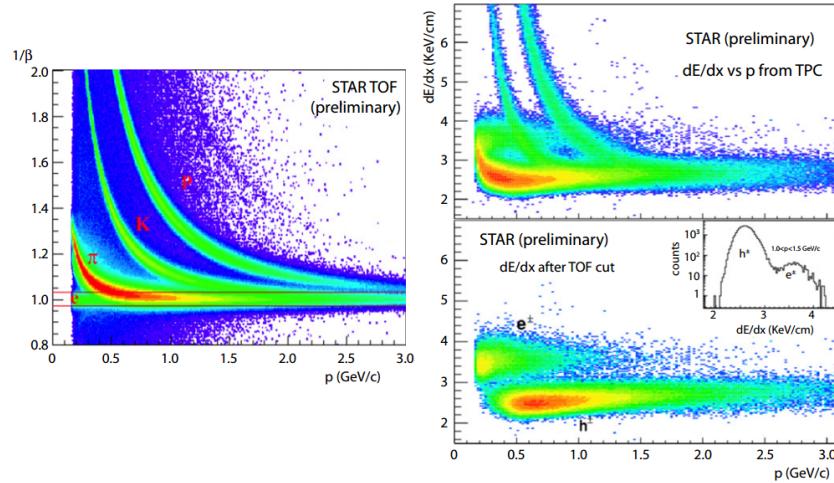

Figure 4.9: Particle identification applied to electrons in the STAR experiment. The identification is performed combining ToF and dE/dx measurements [56].

¹⁹²⁹ Another benefice of using such small gas gaps is the strong reduction of the average avalanche volume and thus of the blind spot on MRPCs leading to an improved rate capability. Multigaps can sustain backgrounds of several kHz/cm² as demonstrated in Figure 4.10.

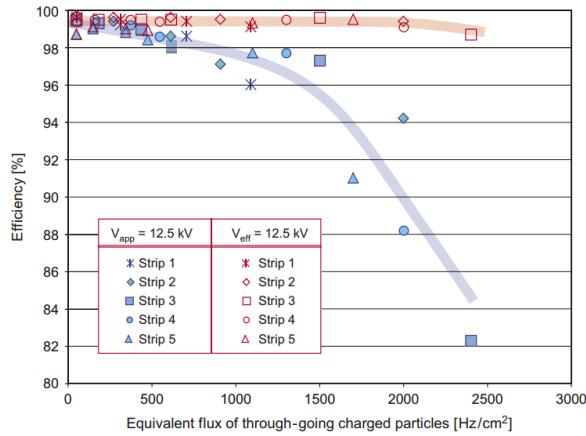

Figure 4.10: Comparison of the detector performance of ALICE ToF MRPC [57] at fixed applied voltage (in blue) and at fixed effective voltage (in red). The effective voltage is kept fixed by increasing the applied voltage accordingly to the current drawn by the detector.

¹⁹³² 4.2.2.3 Charge distribution and performance limitations

¹⁹³³ The direct consequence of the different RPC layouts is a variation of intrinsic time resolution of the ¹⁹³⁴ RPC as the gap size decreases. An advantage is given to multigaps whose design use sub-millimeter ¹⁹³⁵ gas volumes providing very consistent signals.

1936 On the charge spectrum point of view, each layout has its own advantages. When the double-gap
 1937 has the highest induced over drifting charge ratio, as seen in Figure 4.11, the multigap has a charge
 1938 spectrum strongly detached from the origin, as visible in Figure 4.12. A high induced over drifting
 1939 charge ratio means that the double gap can be safely operated at high threshold or that at similar
 1940 threshold it can be operated with a twice smaller drifting charge, meaning a higher rate capability.
 1941 On the other hand, the strong detachment of the charge spectrum from the origin in the MRPC case
 1942 allows to reach a higher efficiency with increasing threshold as most of the induced charge is not low
 1943 due to the convolution of several single gap spectra. The range of stable efficiency increases with
 1944 the number of gap, as presented in Figure 4.13.

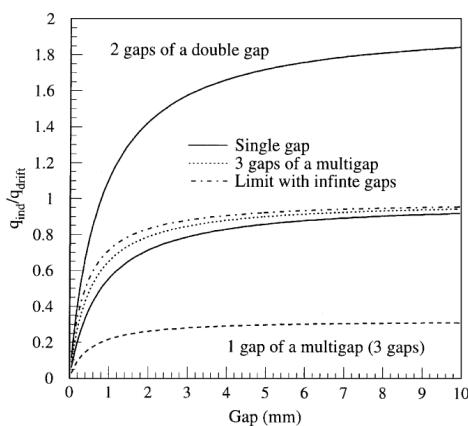

Figure 4.11: Ratio between total induced and drifting charge have been simulated for single gap, double-gap and multigap layouts [58]. The total induced charge for a double-gap RPC is a factor 2 higher than for a multigap.

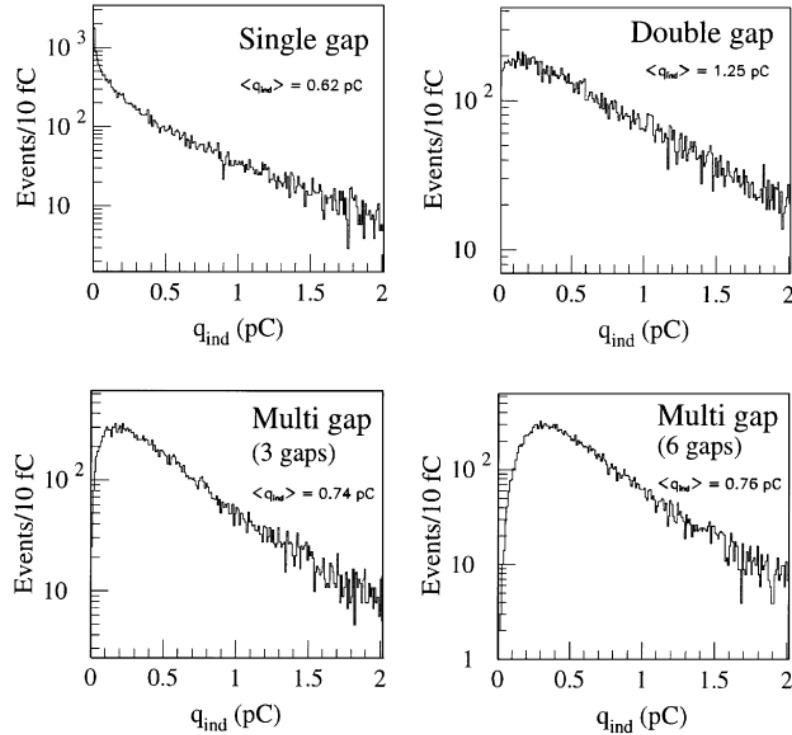

Figure 4.12: Charge spectra have been simulated for single gap, double-gap and multigap layouts [58]. It appears that when single gap shows a decreasing spectrum, double and multigap layouts exhibit a spectrum whose peak is detached from the origin. The detachment gets stronger as the number of gaps increases.

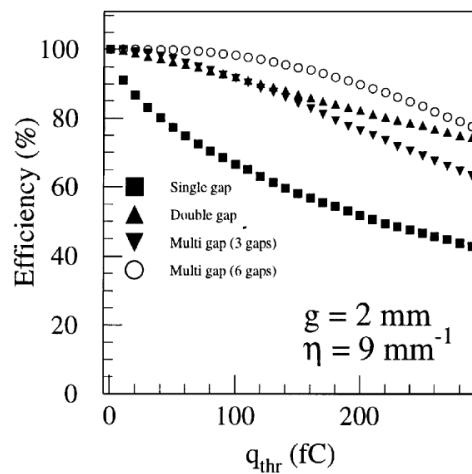

Figure 4.13: The maximal theoretical efficiency is simulated for single gap, double-gap and multigap layouts [58] at a constant gap thickness of 2 mm and using an effective Townsend coefficient of 9 mm^{-1} .

Longevity studies and Consolidation of the present CMS RPC subsystem

1950 5.1 Resistive Plate Chambers at CMS

1951 5.1.1 Overview

1952 The Resistive Plate Chambers (RPC) system, located in both barrel and endcap regions, provides a
1953 fast, independent muon trigger with a looser p_T threshold over a large portion of the pseudorapidity
1954 range ($|\eta| < 1.6$) [add reconstruction].

1955

1956 During High-Luminosity LHC (HL-LHC) operations the expected conditions in terms of back-
1957 ground and pile-up will make the identification and correct P_T assignment a challenge for the Muon
1958 system. The goal of RPC upgrade is to provide additional hits to the Muon system with precise tim-
1959 ing. All these informations will be elaborated by the trigger system in a global way enhancing the
1960 performance of the trigger in terms of efficiency and rate control. The RPC Upgrade is based on two
1961 projects: an improved Link Board System and the extension of the RPC coverage up to $|\eta| = 2.4$.
1962 [FIXME 2.4 or 2.5?]

1963 The Link Board system, that will be described in section xxx, is responsible to process, syn-
1964 chronize and zero-suppress the signals coming from the RPC front end boards. The Link Board
1965 components have been produced between 2006 and 2007 and will be subjected to aging and failure
1966 in the long term. The upgraded Link Board system will overcome the aging problems described in
1967 section xxx and will allow for a more precise timing information to the RPC hits from 25 to 1 ns [ref
1968 section xxx].

1969 The extension of the RPC system up to $|\eta| = 2.1$ was already planned in the CMS TDR [ref
1970 cmstdr] and staged because of budget limitations and expected background rates higher than the rate
1971 capability of the present CMS RPCs in that region. An extensive R&D program has been done in
1972 order to develop an improved RPC that fulfills the CMS requirements. Two new RPC layers in the
1973 innermost ring of stations 3 and 4 will be added with benefits to the neutron-induced background

1974 reduction and efficiency improvement for both trigger and offline reconstruction.

1975 5.1.2 The present RPC system

1976 The RPC system is organized in 4 stations called RB1 to RB4 in the barrel region, and RE1 to RE4
 1977 in the endcap region. The innermost barrel stations, RB1 and RB2, are instrumented with 2 layers
 1978 of RPCs facing the innermost (RB1in and RB2in) and outermost (RB1out and RB2out) sides of the
 1979 DT chambers. Every chamber is then divided from the read-out point of view into 2 or 3 η partitions
 1980 called “rolls”. The RPC system consist of 480 barrel chambers and 576 endcap chambers. Details
 1981 on the geometry are discussed in the paper [ref to geo paper].

1982 The CMS RPC chamber is a double-gap, operated in avalanche mode to ensure reliable operation
 1983 at high rates. Each RPC gap consists of two 2-mm-thick resistive High-Pressure Laminate (HPL)
 1984 plates separated by a 2-mm-thick gas gap. The outer surface of the HPL plates is coated with a thin
 1985 conductive graphite layer, and a voltage is applied. The RPCs are operated with a 3-component,
 1986 non-flammable gas mixture consisting of 95.2% freon ($C_2H_2F_4$, known as R134a), 4.5% isobutane
 1987 ($i-C_4H_{10}$), and 0.3% sulphur hexafluoride (SF_6) with a relative humidity of 40% - 50%. Readout
 1988 strips are aligned in η between the 2 gas gaps. [\[Add a sentence on FEBs.\]](#)

1989 The discriminated signals coming from the Front End boards feed via twisted cables (10 to 20 m
 1990 long) the Link Board System located in UXC on the balconies around the detector. The Link System
 1991 consist of the 1376 Link Boards (LBs) and the 216 Control Boards (CBs), placed in 108 Link Boxes.
 1992 The Link Box is a custom crate (6U high) with 20 slots (for two CBs and eighteen LBs). The Link
 1993 Box contains custom backplane to which the cables from the chambers are connected, as well as the
 1994 cables providing the LBs and CBs power supply and the cables for the RPC FEBs control with use
 1995 of the I2C protocol (trough the CB). The backplane itself contains only connectors (and no any other
 1996 electronic devices).

1997 The Link Board has 96 input channels (one channel corresponds to one RPC strip). The input
 1998 signals are the ~ 100 ns binary pulses which are synchronous to the RPC hits, but not to the LHC
 1999 clock (which drives the entire CMS electronics). Thus the first step of the FEB signals processing
 2000 is synchronization, i.e. assignment of the signals to the BXes (25 ns periods). Then the data are
 2001 compressed with a simple zero-suppressing algorithm (the input channels are grouped into 8 bit
 2002 partitions, only the partitions with at least one nonzero bit are selected for each BX). Next, the non-
 2003 empty partitions are time-multiplexed i.e. if there are more than one such partition in a given BX,
 2004 they are sent one-by-one in consecutive BXes. The data from 3 neighbouring LBs are concentrated
 2005 by the middle LB which contains the optical transmitter for sending them to the USC over a fiber at
 2006 1.6 Gbps.

2007 The Control Boards provide the communication of the control software with the LBs via the
 2008 FEC/CCU system. The CBs are connected into token rings, each ring consists of 12 CBs of one
 2009 detector tower and a FEC mezzanine board placed on the CCS board located in the VME crate in
 2010 the USC. In total, there are 18 rings in the entire Link System. The CBs also perform automatic
 2011 reloading of the LB's firmware which is needed in order to avoid accumulation of the radiation
 2012 induced SEUs in the LBs firmware.

2013 Both LBs and CB are based on the Xilinx Spartan III FPGAs, the CB additionally contains
 2014 radiation-tolerant (FLASH based) FPGA Actel ProAsicPlus.

2015 The High Voltage power system is located in USC, not exposed to radiation and easily accessible
 2016 for any reparation. A single HV channel powers 2 RPC chambers both in the barrel and endcap
 2017 regions. The Low Voltage boards are located in UXC on the balconies and provide the voltage to the

2018 front end electronics.

2019 5.1.3 Pulse processing of CMS RPCs

2020 Signals induced by cosmic particle in the RPC strips are shaped by standard CMS RPC Front-End
2021 Electronics (FEE) following the scheme of Figure 5.1. On a first stage, analogic signals are amplified
2022 and then sent to the Constant Fraction Discriminator (CFD) described in Figure 5.2. At the end of
2023 the chain, 100 ns long pulses are sent in the LVDS output. These output signal are sent on one side to
2024 a V1190A Time-to-Digital Converter (TDC) module from CAEN and on the other to an OR module
2025 to count the number of detected signals. Trigger and hit coïncidences are monitored using scalers.
2026 The TDC is used to store the data into ROOT files. These files are thus analysed to understand the
2027 detectors performance.

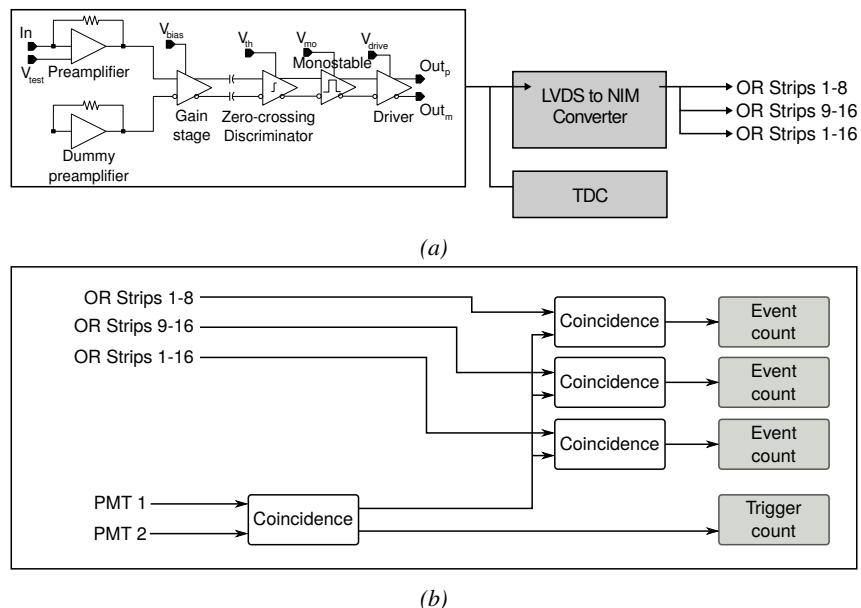

Figure 5.1: Signals from the RPC strips are shaped by the FEE described on Figure 5.1a. Output LVDS signals are then read-out by a TDC module connected to a computer or converted into NIM and sent to scalers. Figure 5.1b describes how these converted signals are put in coincidence with the trigger.

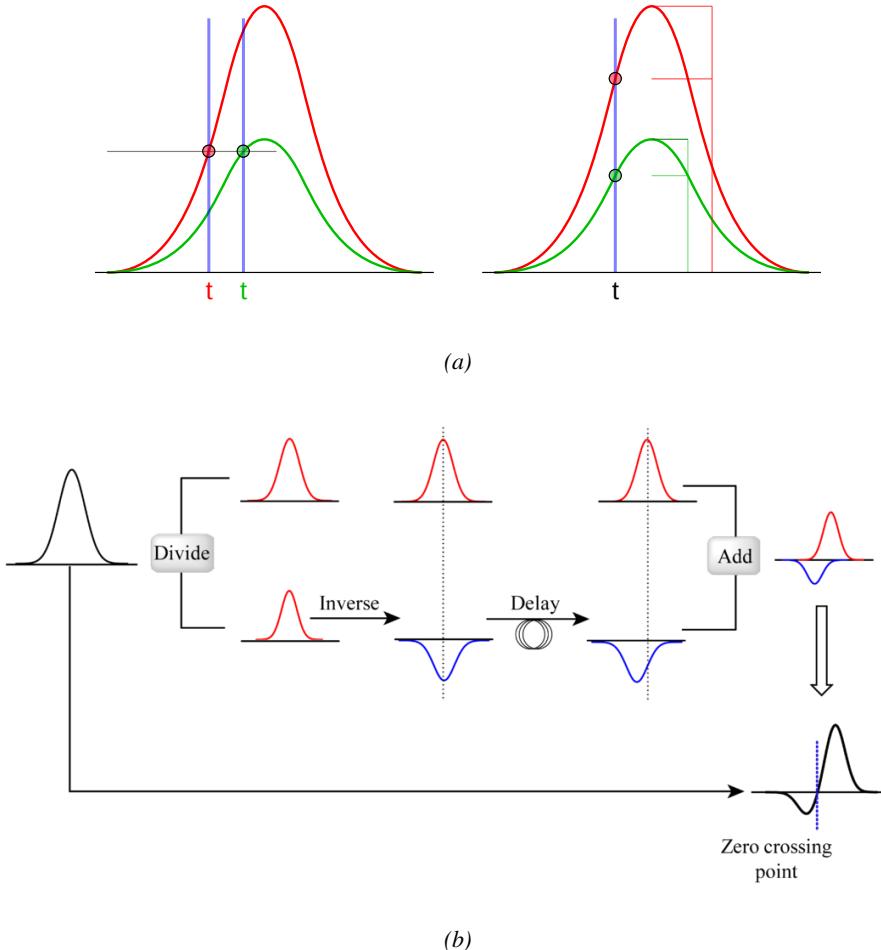

Figure 5.2: Description of the principle of a CFD. A comparison of threshold triggering (left) and constant fraction triggering (right) is shown in Figure 5.2a. Constant fraction triggering is obtained thanks to zero-crossing technique as explained in Figure 5.2b. The signal arriving at the input of the CFD is split into three components. A first one is delayed and connected to the inverting input of a first comparator. A second component is connected to the noninverting input of this first comparator. A third component is connected to the noninverting input of another comparator along with a threshold value connected to the inverting input. Finally, the output of both comparators is fed through an AND gate.

2028 5.2 Testing detectors under extreme conditions

2029 The upgrade from LHC to HL-LHC will increase the peak luminosity from $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ to reach
 2030 $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$, increasing in the same way the total expected background to which the RPC
 2031 system will be subjected to. Composed of low energy gammas and neutrons from $p\text{-}p$ collisions, low
 2032 momentum primary and secondary muons, puch-through hadrons from calorimeters, and particles
 2033 produced in the interaction of the beams with collimators, the background will mostly affect the
 2034 regions of CMS that are the closest to the beam line, i.e. the RPC detectors located in the endcaps.
 2035 [To update.]

2036

2037 The 2016 data allowed to study the values of the background rate in all RPC system. In Figure 5.3, the distribution of the chamber background hit rate per unit area is shown at a luminosity
 2038 of $5 \times 10^{34} \text{ cm}^{-2} \cdot \text{s}^{-1}$ linearly extrapolating from data collected in 2016 [ref mentioning the linear
 2039 dependency of rate vs lumi]. The maximum rate per unit area at HL-LHC conditions is expected to
 2040 be of the order of 600 Hz/cm^2 (including a safety factor 3). Nevertheless, Fluka simulations have
 2041 conducted in order to understand the background at HL-LHC conditions. The comparison to the
 2042 data has shown, in Figure 5.4, a discrepancy of a factor 2 even though the order of magnitude is
 2043 consistent. [Understand mismatch.]
 2044

2045

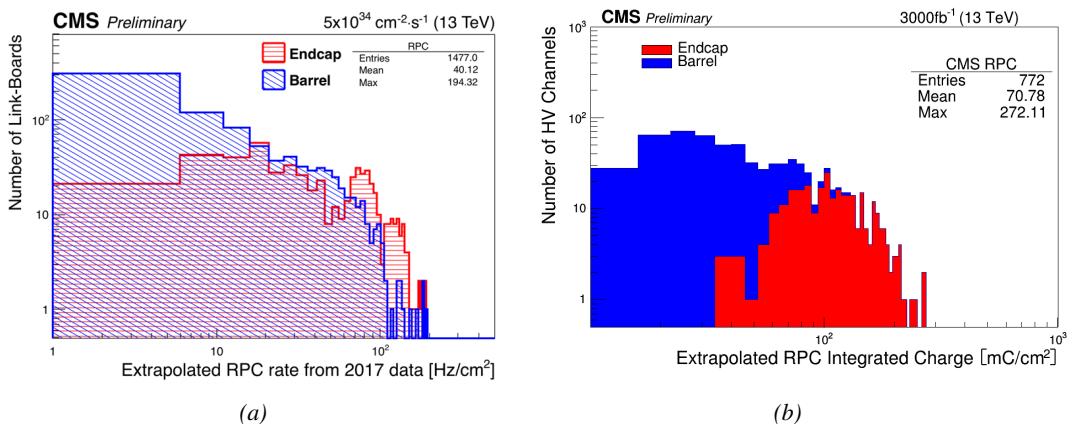

Figure 5.3: Figure 5.3a: The integrated charge per region (Barrel, Endcap) is extrapolated to HL-LHC integrated luminosity (3000 fb^{-1}) using the data accumulated in 2016 in every HV channels. Figure 5.3b: The hit rate per region (Barrel, Endcap) is linearly extrapolated to HL-LHC highest instantaneous luminosity ($5 \times 10^{34} \text{ cm}^{-2} \text{s}^{-1}$) using the rate as a function of instantaneous luminosity recorded by RPCs in 2017 showing a linear dependence.

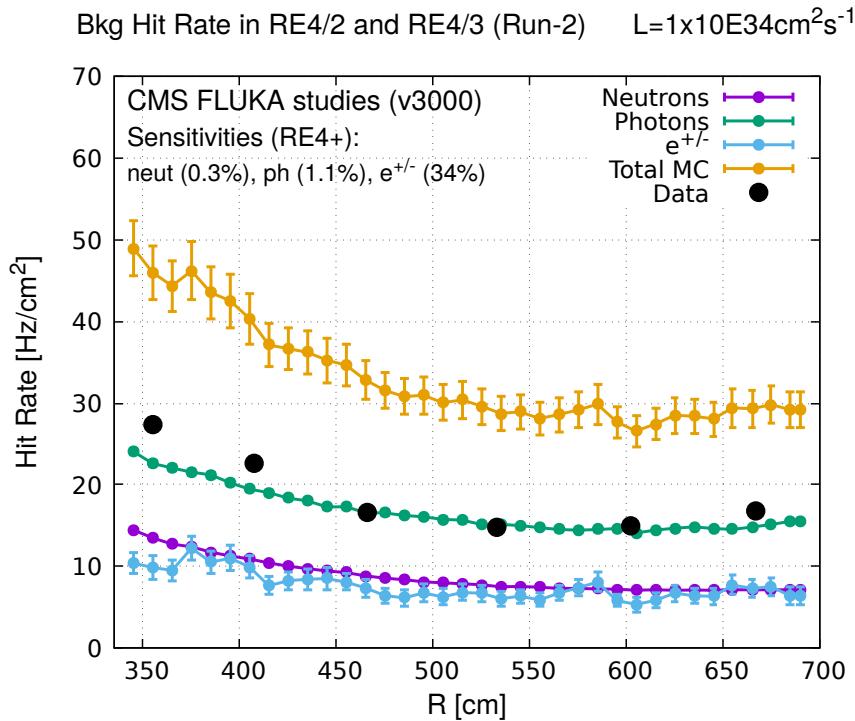

Figure 5.4: Background Fluka simulation compared to 2016 Data at $L = 10^{34} \text{ cm}^{-2} \cdot \text{s}^{-1}$ in the fourth endcap disk region. A mismatch in between simulation and data can be observed. [\[To be understood.\]](#)

In the past, extensive long-term tests were carried out at several gamma and neutron facilities certifying the detector performance. Both full size and small prototype RPCs have been irradiated with photons up to an integrated charge of $\sim 0.05 \text{ C/cm}^2$ and $\sim 0.4 \text{ C/cm}^2$, respectively [59, 60]. During Run-I, the RPC system provided stable operation and excellent performance and did not show any aging effects for integrated charge of the order of 0.01 C/cm^2 . Projections on currents from 2016 Data, has allowed to determine that the total integrated charge, by the end of HL-LHC, would be of the order of 1 C/cm^2 (including a safety factor 3). [\[Corresponding figure needed.\]](#)

2053

2054 5.2.1 The Gamma Irradiation Facilities

2055 5.2.1.1 GIF

2056 Located in the SPS West Area at the downstream end of the X5 test beam, the Gamma Irradiation
 2057 Facility (GIF) was a test area in which particle detectors were exposed to a particle beam in presence
 2058 of an adjustable gamma background [61]. Its goal was to reproduce background conditions these
 2059 detectors would suffer in their operating environment at LHC. GIF layout is shown in Figure 5.5.
 2060 Gamma photons are produced by a strong ^{137}Cs source installed in the upstream part of the zone
 2061 inside a lead container. The source container includes a collimator, designed to irradiate a $6 \times 6 \text{ m}^2$
 2062 area at 5 m maximum to the source. A thin lens-shaped lead filter helps providing with a uniform
 2063 outcoming flux in a vertical plane, orthogonal to the beam direction. The principal collimator hole
 2064 provides a pyramidal aperture of $74^\circ \times 74^\circ$ solid angle and provides a photon flux in a pyramidal vol-

2065 ume along the beam axis. The photon rate is controled by further lead filters allowing the maximum
 2066 rate to be limited and to vary within a range of four orders of magnitude. Particle detectors under test
 2067 are then placed within the pyramidal volume in front of the source, perpendicularly to the beam line
 2068 in order to profit from the homogeneous photon flux. Adjusting the background flux of photons can
 2069 then be done by using the filters and choosing the position of the detectors with respect to the source.
 2070

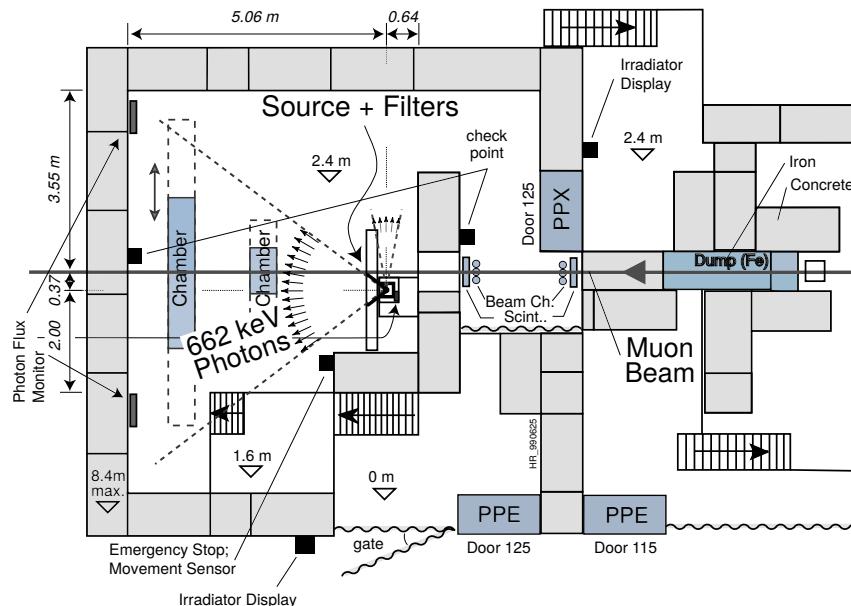

Figure 5.5: Layout of the test beam zone called X5c GIF at CERN. Photons from the radioactive source produce a sustained high rate of random hits over the whole area. The zone is surrounded by 8 m high and 80 cm thick concrete walls. Access is possible through three entry points. Two access doors for personnel and one large gate for material. A crane allows installation of heavy equipment in the area.

2071 As described on Figure 5.6, the ^{137}Cs source emits a 662 keV photon in 85% of the decays. An
 2072 activity of 740 GBq was measured on the 5th March 1997. To estimate the strength of the flux in
 2073 2014, it is necessary to consider the nuclear decay through time assiciated to the Cesium source
 2074 whose half-life is well known ($t_{1/2} = (30.05 \pm 0.08)$ y). The GIF tests were done in between the
 2075 20th and the 31st of August 2014, i.e. at a time $t = (17.47 \pm 0.02)$ y resulting in an attenuation of
 2076 the activity from 740 GBq in 1997 to 494 GBq in 2014.
 2077

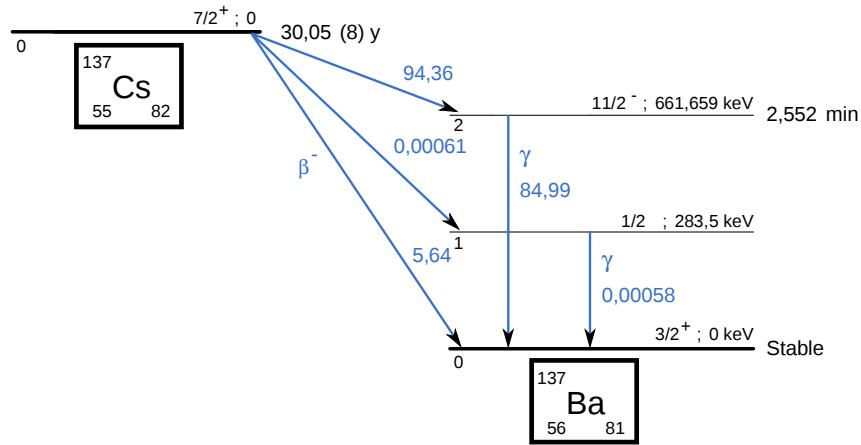

Figure 5.6: ^{137}Cs decays by β^- emission to the ground state of ^{137}Ba ($\text{BR} = 5.64\%$) and via the 662 keV isomeric level of ^{137}Ba ($\text{BR} = 94.36\%$) whose half-life is 2.55 min.

5.2.1.2 GIF++

The new Gamma Irradiation Facility (GIF++), located in the SPS North Area at the downstream end of the H4 test beam, has replaced its predecessor during LS1 and has been operational since spring 2015 [62]. Like GIF, GIF++ features a ^{137}Cs source of 662 keV gamma photons, their fluence being controlled with a set of filters of various attenuation factors. The source provides two separated large irradiation areas for testing several full-size muon detectors with continuous homogeneous irradiation, as presented in Figure 5.7.

2085

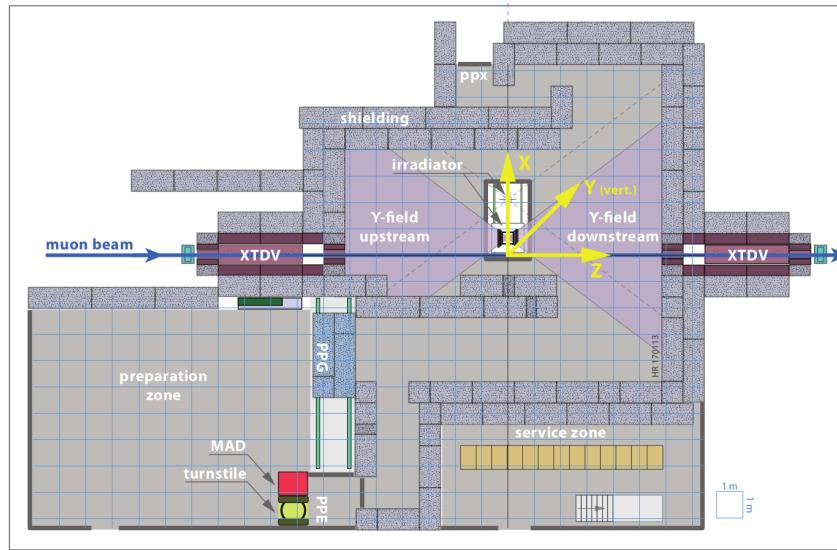

Figure 5.7: Floor plan of the GIF++ facility. When the facility downstream of the GIF++ takes electron beam, a beam pipe is installed along the beam line (z -axis). The irradiator can be displaced laterally (its center moves from $x = 0.65 \text{ m}$ to 2.15 m), to increase the distance to the beam pipe.

The source activity was measured to be about 13.5 TBq in March 2016. The photon flux being far greater than HL-LHC expectations, GIF++ provides an excellent facility for accelerated aging tests of muon detectors.

2089

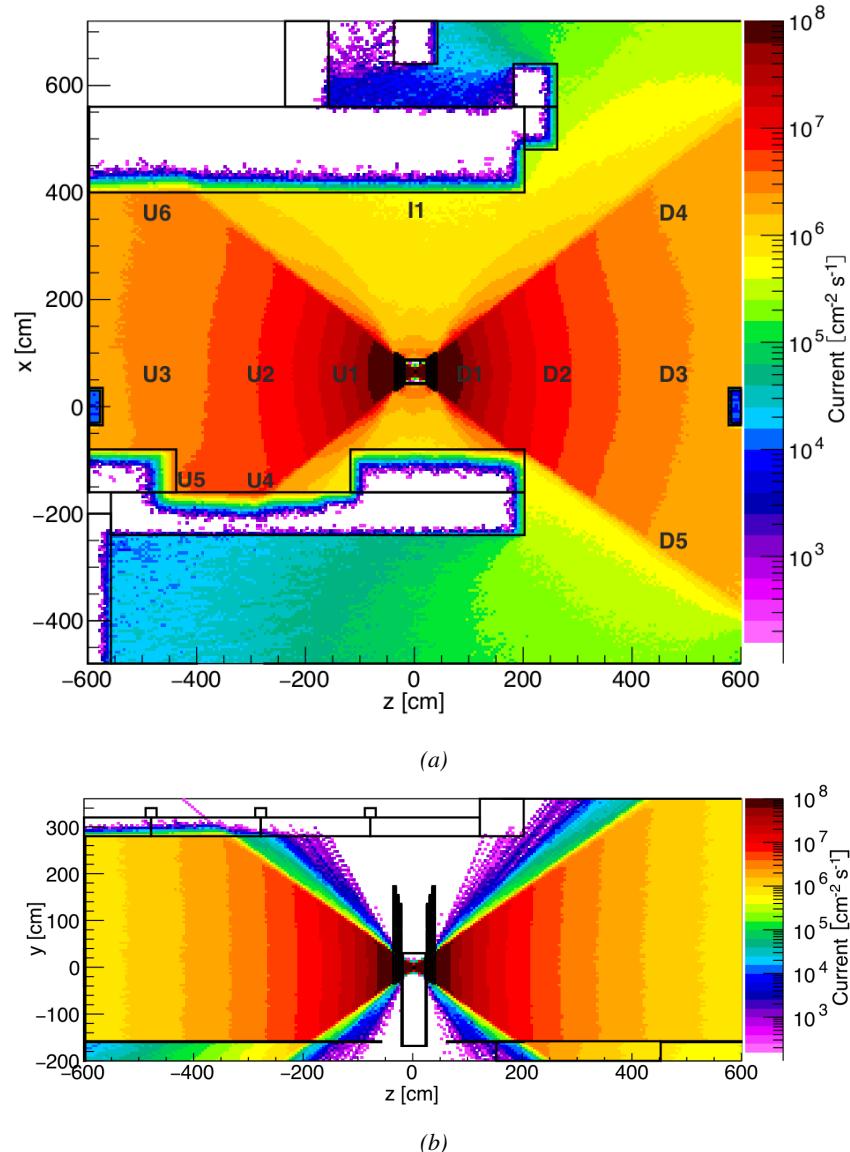

Figure 5.8: Simulated unattenuated current of photons in the xz plane (Figure 5.8a) and yz plane (Figure 5.8b) through the source at $x = 0.65$ m and $y = 0$ m. With angular correction filters, the current of 662 keV photons is made uniform in xy planes.

2090

The source is situated in the muon beam line with the muon beam being available a few times a year. The H4 beam, composed of muons with a momentum of about 150 GeV/c, passes through the GIF++ zone and is used to study the performance of the detectors. Its flux is of 104 particles/ s/cm^2

2091

2092

2093 focused in an area similar to $10 \times 10 \text{ cm}^2$. Therefore, with properly adjusted filters, one can imitate
 2094 the HL-LHC background and study the performance of muon detectors with their trigger/readout
 2095 electronics in HL-LHC environment.

2096

2097 5.3 Preliminary tests at GIF

2098 5.3.1 Resistive Plate Chamber test setup

2099 During summer 2014, preliminary tests have been conducted in the GIF area on a newly produced
 2100 RE4/2 chamber labelled RE-4-2-BARC-161. This chamber has been placed into a trolley covered
 2101 with a tent. The position of the RPC inside the tent and of the tent related to the source is described
 2102 in Figure 5.9. To test this CMS RPC, three different absorber settings were used. First of all,
 2103 measurements were done with fully opened source. Then, to complete this preliminary study, the
 2104 gamma flux has been attenuated from a factor 2 and a factor 5. The expected gamma flux at the level
 2105 of our detector will be discussed in subsection ??.

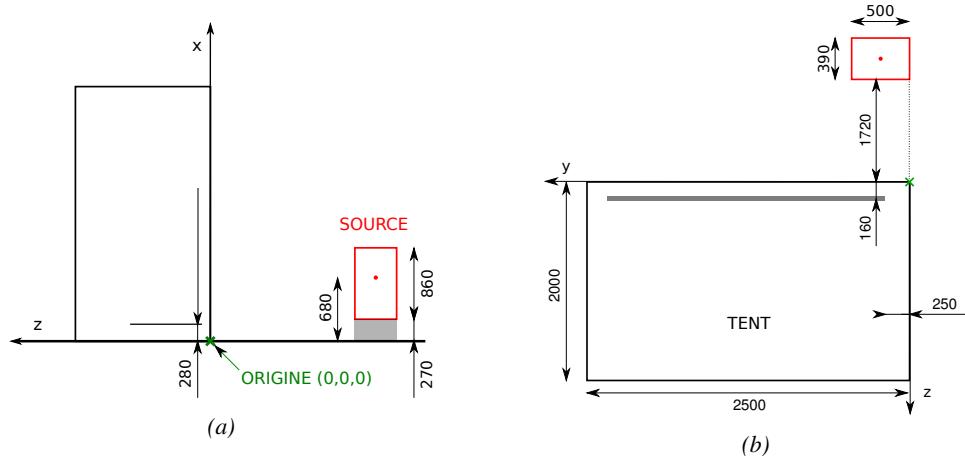

Figure 5.9: Description of the RPC setup. Dimensions are given in mm. A tent containing RPCs is placed at 1720 mm from the source container. The source is situated in the center of the container. RE-4-2-BARC-161 chamber is 160 mm inside the tent. This way, the distance between the source and the chambers plan is 2060 mm. Figure 5.9a provides a side view of the setup in the xz plane while Figure 5.9b shows a top view in the yz plane.

Figure 5.10: RE-4-2-BARC-I61 chamber is inside the tent as described in Figure 5.9. In the top right, the two scintillators used as trigger can be seen. This trigger system has an inclination of 10° relative to horizontal and is placed above half-partition B2 of the RPCs. PMT electronics are shielded thanks to lead blocks placed in order to protect them without stopping photons from going through the scintillators and the chamber.

2106 At the time of the tests, the beam not being operational anymore, a trigger composed of 2 plastic
 2107 scintillators has been placed in front of the setup with an inclination of 10 deg with respect to the
 2108 detector plane in order to look at cosmic muons. Using this particular trigger layout, shown on Fig-
 2109 ure 5.10, leads to a cosmic muon hit distribution into the chamber similar to the one in Figure 5.11.
 2110 Measured without gamma irradiation, two peaks can be seen on the profile of partition B, centered
 2111 on strips 52 and 59. Section ?? will help us understand that these two peaks are due respectively to
 2112 forward and backward coming cosmic particles where forward coming particles are first detected by
 2113 the scintillators and then the RPC while the backward coming muons are first detected in the RPC.

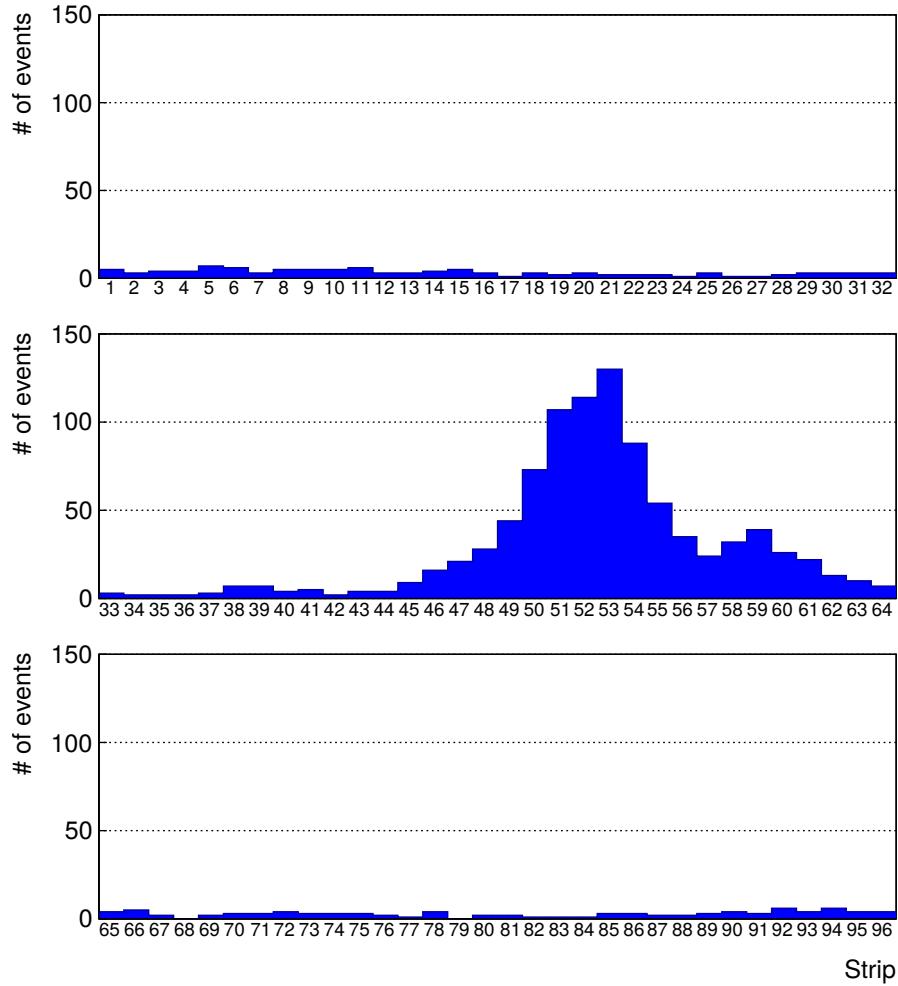

Figure 5.11: Hit distributions over all 3 partitions of RE-4-2-BARC-161 chamber is showed on these plots. Top, middle and bottom figures respectively correspond to partitions A, B, and C. These plots show that some events still occur in other half-partitions than B2, which corresponds to strips 49 to 64, in front of which the trigger is placed, contributing to the inefficiency of detection of cosmic muons. In the case of partitions A and C, the very low amount of data can be interpreted as noise. On the other hand, it is clear that a little portion of muons reach the half-partition B1, corresponding to strips 33 to 48.

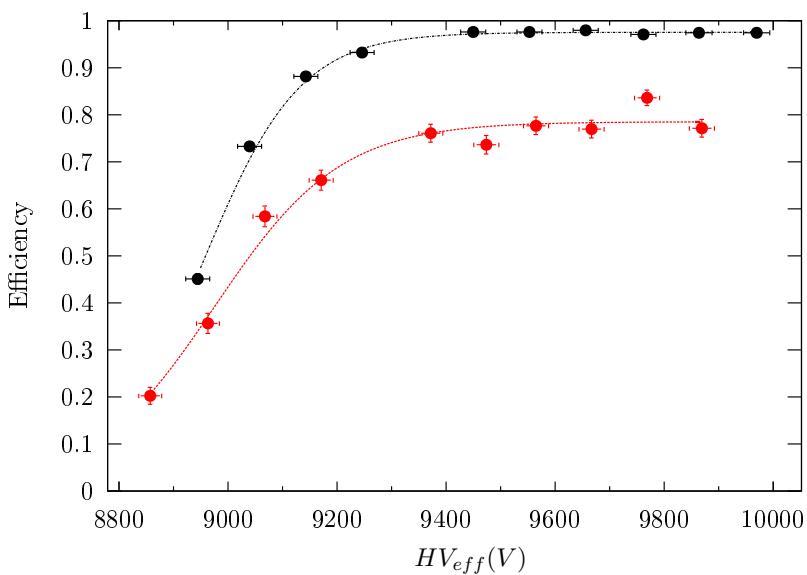

5.3.2 Data Acquisition

5.3.3 Geometrical acceptance of the setup layout to cosmic muons

In order to profit from a constant gamma irradiation, the detectors inside of the GIF bunker need to be placed in a plane orthogonal to the beam line. The muon beam that used to be available was meant to test the performance of detectors under test. This beam not being active anymore, another solution to test detector performance had to be used. Thus, it has been decided to use cosmic muons detected through a telescope composed of two scintillators. Lead blocks were used as shielding to

2121 protect the photomultipliers from gammas as can be seen from Figure 5.10.

2122 An inclination has been given to the cosmic telescope to maximize the muon flux. A good com-
 2123 promise had to be found between good enough muon flux and narrow enough hit distribution to
 2124 be sure to contain all the events into only one half partitions as required from the limited available
 2125 readout hardware. Nevertheless, a consequence of the misplaced trigger, that can be seen as a loss
 2126 of events in half-partition B1 in Figure 5.11, is an inefficiency. Nevertheless, the inefficiency of ap-
 2127 proximately 20 % highlighted in Figure 5.12 by comparing the performance of chamber BARC-161
 2128 in 904 and at GIF without irradiation seems too important to be explained only by the geometri-
 2129 cal acceptance of the setup itself. Simulations have been conducted to show how the setup brings
 2130 inefficiency.

2131 *Figure 5.12: Results are derived from data taken on half-partition B2 only. On the 18th of June 2014, data
 2132 has been taken on chamber RE-2-BARC-161 at building 904 (Prevessin Site) with cosmic muons providing us a
 2133 reference efficiency plateau of $(97.54 \pm 0.15)\%$ represented by a black curve. A similar measurement has been
 2134 done at GIF on the 21st of July with the same chamber giving a plateau of $(78.52 \pm 0.94)\%$ represented by a
 2135 red curve.*

2136 5.3.3.1 Description of the simulation layout

2137 The layout of GIF setup has been reproduced and incorporated into a Monte Carlo (MC) simulation
 2138 to study the influence of the disposition of the telescope on the final distribution measured by the
 2139 RPC. A 3D view of the simulated layout is given into Figure 5.13. Muons are generated randomly
 2140 in a horizontal plane located at a height corresponding to the lowest point of the PMTs. This way,
 2141 the needed size of the plane in order to simulate events happening at very big azimuthal angles (i.e.
 $\theta \approx \pi$) can be kept relatively small. The muon flux is designed to follow the usual $\cos^2\theta$ distribution
 2142 for cosmic particle. The goal of the simulation is to look at muons that pass through the muon
 2143 telescope composed of the two scintillators and define their distribution onto the RPC plane. During
 2144 the reconstruction, the RPC plane is then divided into its strips and each muon track is assigned to a
 2145 strip.

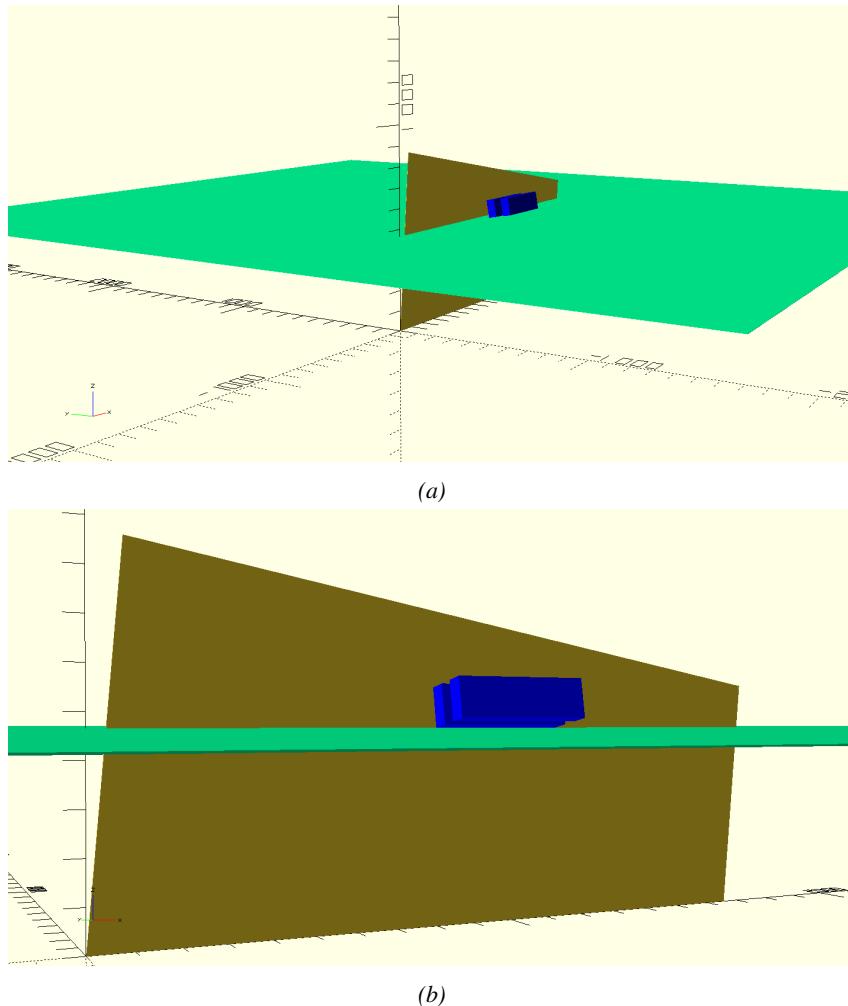

Figure 5.13: Representation of the layout used for the simulations of the test setup. The RPC is represented as a yellow trapezoid while the two scintillators as blue cuboids looking at the sky. A green plane corresponds to the muon generation plane within the simulation. Figure 5.9a shows a global view of the simulated setup. Figure 5.9b shows a zoomed view that allows to see the 2 scintillators as well as the full RPC plane.

In order to further refine the quality of the simulation and understand deeper the results the dependance of the distribution has been studied for a range of telescope inclinations. Moreover, the threshold applied on the PMT signals has been included into the simulation in the form of a cut. In the approximation of uniform scintillators, it has been considered that the threshold can be understood as the minimum distance particles need to travel through the scintillating material to give a strong enough signal. Particles that travel a distance smaller than the set "threshold" are thus not detected by the telescope and cannot trigger the data taking. Finally, the FEE threshold also has been considered in a similar way. The mean momentum of horizontal cosmic rays is higher than those of vertical ones but the stopping power of matter for momenta ranging from 1 GeV to 1 TeV stays comparable. It is then possible to assume that the mean number of primary e^-/ion pairs per unit length will stay similar and thus, depending on the applied discriminator threshold, muons with

2153 the shortest path through the gas volume will deposit less charge and induce a smaller signal on the
 2154 pick-up strips that could eventually not be detected. These two thresholds also restrain the overall
 2155 geometrical acceptance of the system.

2156 5.3.3.2 Simulation procedure

2157 The simulation software has been designed using C++ and the output data is saved into ROOT
 2158 histograms. Simulations start for a threshold T_{scint} varying in a range from 0 to 45 mm in steps
 2159 of 5 mm, where $T_{scint} = 0$ mm corresponds to the case where there isn't any threshold apply on
 2160 the input signal while $T_{scint} = 45$ mm, which is the scintillator thickness, is the case where muons
 2161 cannot arrive orthogonally onto the scintillator surface. For a given T_{scint} , a set of RPC thresholds
 2162 are considered. The RPC threshold, T_{RPC} varies from 2 mm, the thickness of the gas volume, to
 2163 3 mm in steps of 0.25 mm. For each $(T_{scint}; T_{RPC})$ pair, $N_\mu = 10^8$ muons are randomly generated
 2164 inside the muon plane described in the previous paragraph with an azimuthal angle θ chosen to follow
 2165 a $\cos^2\theta$ distribution.

2166 Planes are associated to each surface of the scintillators. Knowing muon position into the muon
 2167 plane and its direction allows us, by assuming that muons travel in a straight line, to compute the
 2168 intersection of the muon track with these planes. Applying conditions to the limits of the surfaces
 2169 of the scintillator faces then gives us an answer to whether or not the muon passed through the
 2170 scintillators. In the case the muon has indeed passed through the telescope, the path through each
 2171 scintillator is computed and muons whose path was shorter than T_{scint} are rejected and are thus
 2172 considered as having not interacted with the setup.

2173 On the contrary, if the muon is labeled as good, its position within the RPC plane is computed
 2174 and the corresponding strip, determined by geometrical tests in the case the distance through the
 2175 gas volume was enough not to be rejected because of T_{RPC} , gets a hit and several histograms
 2176 are filled in order to keep track of the generation point on the muon plane, the intersection points
 2177 of the reconstructed muons within the telescope, or on the RPC plane, the path traveled through
 2178 each individual scintillator or the gas volume, as well as other histograms. Moreover, muons fill
 2179 different histograms whether they are forward or backward coming muons. They are discriminated
 2180 according to their direction components. When a muon is generated, an (x, y, z) position is assigned
 2181 into the muon plane as well as a $(\theta; \phi)$ pair that gives us the direction it's coming from. This way,
 2182 muons satisfying the condition $0 \leq \phi < \pi$ are designated as backward coming muons while muons
 2183 satisfying $\pi \leq \phi < 2\pi$ as forward coming muons.

2184 This simulation is then repeated for different telescope inclinations ranging in between 4 and 20°
 2185 and varying in steps of 2°. Due to this inclination and to the vertical position of the detector under
 2186 test, the muon distribution reconstructed in the detector plane is asymmetrical. The choice as been
 2187 made to chose a skew distribution formula to fit the data built as the multiplication of gaussian and
 2188 sigmoidal curves together. A typical gaussian formula is given as 5.1 and has three free parameters
 2189 as A_g , its amplitude, \bar{x} , its mean value and σ , its root mean square. Sigmoidal curves as given by
 2190 formula 5.2 are functions converging to 0 and A_s as x diverges. The inflection point is given as x_i
 2191 and λ is proportional to the slope at $x = x_i$. In the limit where $\lambda \rightarrow \infty$, the sigmoid becomes a
 2192 step function.

$$g(x) = A_g e^{-\frac{(x-\bar{x})^2}{2\sigma^2}} \quad (5.1)$$

$$s(x) = \frac{A_s}{1 + e^{-\lambda(x-x_i)}} \quad (5.2)$$

Finally, a possible representation of a skew distribution is given by formula 5.3 and is the product of 5.1 and 5.2. Naturally, here $A_{sk} = A_g \times A_s$ and represents the theoretical maximum in the limit where the skew tends to a gaussian function.

$$sk(x) = g(x) \times s(x) = A_{sk} \frac{e^{\frac{-(x-\bar{x})^2}{2\sigma^2}}}{1 + e^{-\lambda(x-x_i)}} \quad (5.3)$$

5.3.3.3 Results

Influence of T_{scint} on the muon distribution

Influence of T_{RPC} on the muon distribution

Influence of the telescope inclination on the muon distribution

Comparison to data taken at GIF without irradiation

5.3.4 Photon flux at GIF

5.3.4.1 Expectations from simulations

In order to understand and evaluate the γ flux in the GIF area, simulations had been conducted in 1999 and published by S. Agosteo et al [61]. Table 5.1 presented in this article gives us the γ flux for different distances D to the source. This simulation was done using GEANT and a Monte Carlo N-Particle (MCNP) transport code, and the flux F is given in number of γ per unit area and unit time along with the estimated error from these packages expressed in %.

Nominal ABS	Photon flux F [$s^{-1}cm^{-2}$]			
	at $D = 50$ cm	at $D = 155$ cm	at $D = 300$ cm	at $D = 400$ cm
1	$0.12 \cdot 10^8 \pm 0.2\%$	$0.14 \cdot 10^7 \pm 0.5\%$	$0.45 \cdot 10^6 \pm 0.5\%$	$0.28 \cdot 10^6 \pm 0.5\%$
2	$0.68 \cdot 10^7 \pm 0.3\%$	$0.80 \cdot 10^6 \pm 0.8\%$	$0.25 \cdot 10^6 \pm 0.8\%$	$0.16 \cdot 10^6 \pm 0.6\%$
5	$0.31 \cdot 10^7 \pm 0.4\%$	$0.36 \cdot 10^6 \pm 1.2\%$	$0.11 \cdot 10^6 \pm 1.2\%$	$0.70 \cdot 10^5 \pm 0.9\%$

Table 5.1: Total photon flux ($E\gamma \leq 662$ keV) with statistical error predicted considering a ^{137}Cs activity of 740 GBq at different values of the distance D to the source along the x -axis of irradiation field [61].

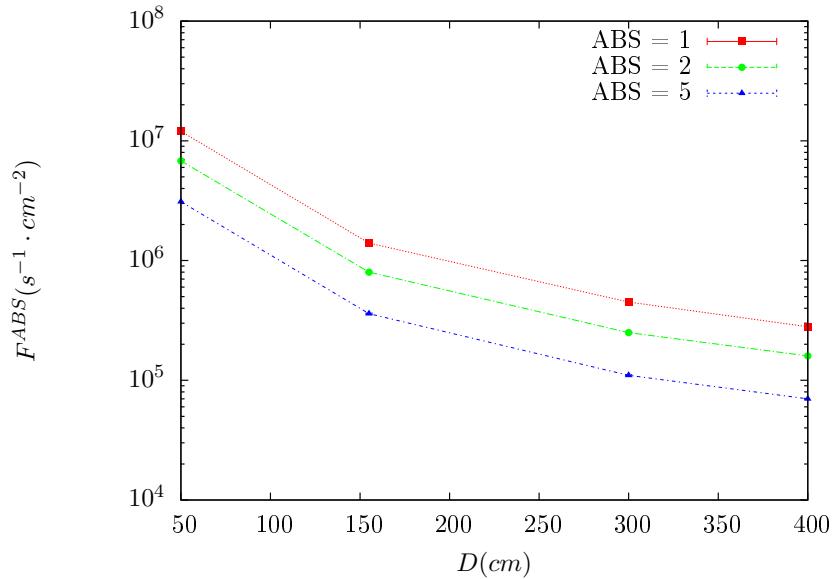

Figure 5.14: γ flux $F(D)$ is plot using values from table 5.1. As expected, the plot shows similar attenuation behaviours with increasing distance for each absorption factors.

The simulation doesn't directly provides us with an estimated flux at the level of our RPC. First of all, it is needed to extract the value of the flux from the available data contained in the original paper and then to estimate the flux in 2014 at the time the experimentation took place. Figure 5.14 that contains the data from Table 5.1. In the case of a pointlike source emitting isotropic and homogeneous gamma radiations, the gamma flux F at a distance D to the source with respect to a reference point situated at D_0 where a known flux F_0 is measured will be expressed like in Equation 5.4, assuming that the flux decreases as $1/D^2$, where c is a fitting factor.

$$F^{ABS} = F_0^{ABS} \times \left(\frac{cD_0}{D} \right)^2 \quad (5.4)$$

By rewriting Equation 5.4, it comes that :

$$c = \frac{D}{D_0} \sqrt{\frac{F^{ABS}}{F_0^{ABS}}} \quad (5.5)$$

$$\Delta c = \frac{c}{2} \left(\frac{\Delta F^{ABS}}{F^{ABS}} + \frac{\Delta F_0^{ABS}}{F_0^{ABS}} \right) \quad (5.6)$$

Finally, using Equation 5.5 and the data in Table 5.1 with $D_0 = 50$ cm as reference point, we can build Table 5.2. It is interesting to note that c for each value of D doesn't depend on the absorption factor.

Nominal ABS	Correction factor c		
	at $D = 155$ cm	at $D = 300$ cm	at $D = 400$ cm
1	$1.059 \pm 0.70\%$	$1.162 \pm 0.70\%$	$1.222 \pm 0.70\%$
2	$1.063 \pm 1.10\%$	$1.150 \pm 1.10\%$	$1.227 \pm 0.90\%$
5	$1.056 \pm 1.60\%$	$1.130 \pm 1.60\%$	$1.202 \pm 1.30\%$

Table 5.2: Correction factor c is computed thanks to formulae 5.5 taking as reference $D_0 = 50$ cm and the associated flux F_0^{ABS} for each absorption factor available in table 5.1.

2219 For the range of D/D_0 values available, it is possible to use a simple linear fit to get the evolution
 2220 of c . The linear fit will then use only 2 free parameters, a and b , as written in Equation 5.7. This gives
 2221 us the results showed in Figure 5.15. Figure 5.15b confirms that using only a linear fit to extract c is
 2222 enough as the evolution of the rate that can be obtained superimposes well on the simulation points.

$$c \left(\frac{D}{D_0} \right) = a \frac{D}{D_0} + b \quad (5.7)$$

$$F^{ABS} = F_0^{ABS} \left(a + \frac{b D_0}{D} \right)^2 \quad (5.8)$$

$$\Delta F^{ABS} = F^{ABS} \left[\frac{\Delta F_0^{ABS}}{F_0^{ABS}} + 2 \frac{\Delta a + \Delta b \frac{D_0}{D}}{a + \frac{b D_0}{D}} \right] \quad (5.9)$$

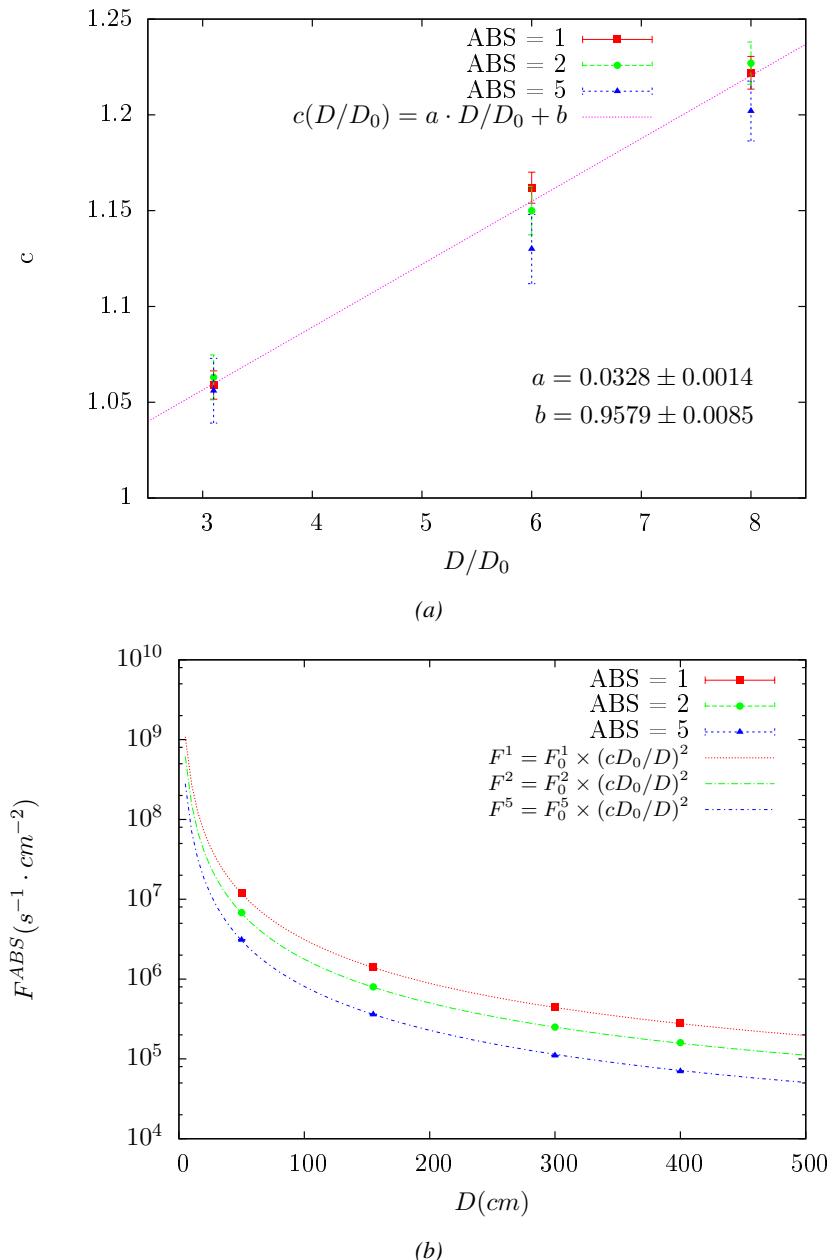

Figure 5.15: Figure 5.15a shows the linear approximation fit done via formulae 5.7 on data from table 5.2. Figure 5.15b shows a comparison of this model with the simulated flux using a and b given in figure 5.15a in formulae 5.4 and the reference value $D_0 = 50\text{cm}$ and the associated flux for each absorption factor F_0^{ABS} from table 5.1

In the case of the 2014 GIF tests, the RPC plane is located at a distance $D = 206$ cm to the source. Moreover, to estimate the strength of the flux in 2014, it is necessary to consider the nuclear decay through time associated to the Cesium source whose half-life is well known ($t_{1/2} = (30.05 \pm 0.08)$ y). The very first source activity measurement has been done on the 5th of March 1997 while the GIF

2227 tests were done in between the 20th and the 31st of August 2014, i.e. at a time $t = (17.47 \pm 0.02)$ y
 2228 resulting in an attenuation of the activity from 740 GBq in 1997 to 494 GBq in 2014. All the needed
 2229 information to extrapolate the flux through our detector in 2014 has now been assembled, leading
 2230 to the Table 5.3. It is interesting to note that for a common RPC sensitivity to γ of $2 \cdot 10^{-3}$, the
 2231 order of magnitude of the estimated hit rate per unit area is of the order of the kHz for the fully
 2232 opened source. Moreover, taking profit of the two working absorbers, it will be possible to scan
 2233 background rates at 0 Hz, ~ 300 Hz as well as ~ 600 Hz. Without source, a good estimate of the
 2234 intrinsic performance will be available. Then at 300 Hz, the goal will be to show that the detectors
 2235 fulfill the performance certification of CMS RPCs. Then a first idea of the performance of the
 2236 detectors at higher background will be provided with absorption factors 2 (~ 600 Hz) and 1 (no
 2237 absorption). *[Here I will also put a reference to the plot showing the estimated background rate at
 2238 the level of RE3/1 in the case of HL-LHC but this one being in another chapter, I will do it later.]*

Nominal ABS	Photon flux F [$s^{-1}cm^{-2}$]			Hit rate/unit area [$Hz cm^{-2}$] at $D^{2014} = 206$ cm
	at $D_0^{1997} = 50$ cm	at $D^{1997} = 206$ cm	at $D^{2014} = 206$ cm	
1	$0.12 \cdot 10^8 \pm 0.2\%$	$0.84 \cdot 10^6 \pm 0.3\%$	$0.56 \cdot 10^6 \pm 0.3\%$	1129 ± 32
2	$0.68 \cdot 10^7 \pm 0.3\%$	$0.48 \cdot 10^6 \pm 0.3\%$	$0.32 \cdot 10^6 \pm 0.3\%$	640 ± 19
5	$0.31 \cdot 10^7 \pm 0.4\%$	$0.22 \cdot 10^6 \pm 0.3\%$	$0.15 \cdot 10^6 \pm 0.3\%$	292 ± 9

Table 5.3: The data at D_0 in 1997 is taken from [61]. In a second step, using Equations 5.8 and 5.9, the flux at D can be estimated in 1997. Then, taking into account the attenuation of the source activity, the flux at D can be estimated at the time of the tests in GIF in 2014. Finally, assuming a sensitivity of the RPC to γ $s = 2 \cdot 10^{-3}$, an estimation of the hit rate per unit area is obtained.

²²³⁹ **5.3.4.2 Dose measurements**

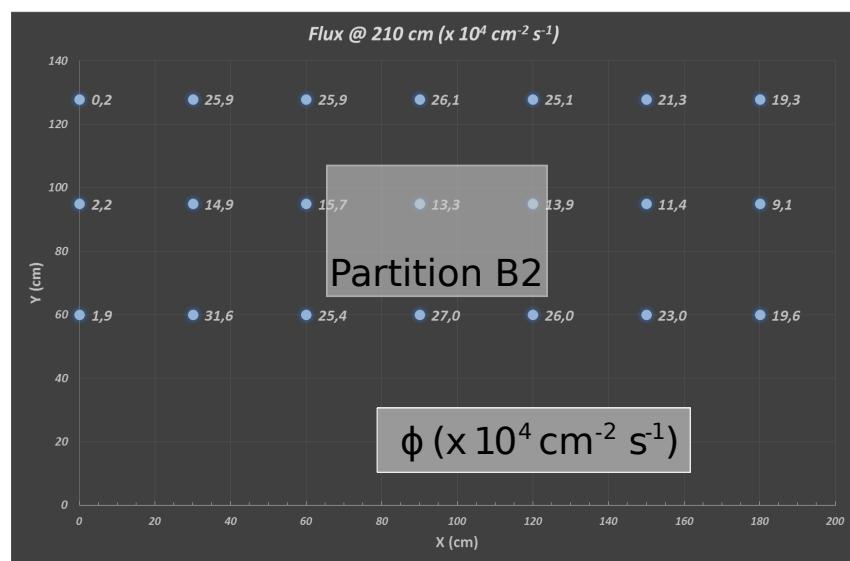

Figure 5.16: Dose measurements has been done in a plane corresponding to the tents front side. This plan is 1900 mm away from the source. As explained in the first chapter, a lens-shaped lead filter provides a uniform photon flux in the vertical plan orthogonal to the beam direction. If the second line of measured fluxes is not taken into account because of lower values due to experimental equipments in the way between the source and the tent, the uniformity of the flux is well showed by the results.

²²⁴⁰ **5.3.5 Results and discussions**

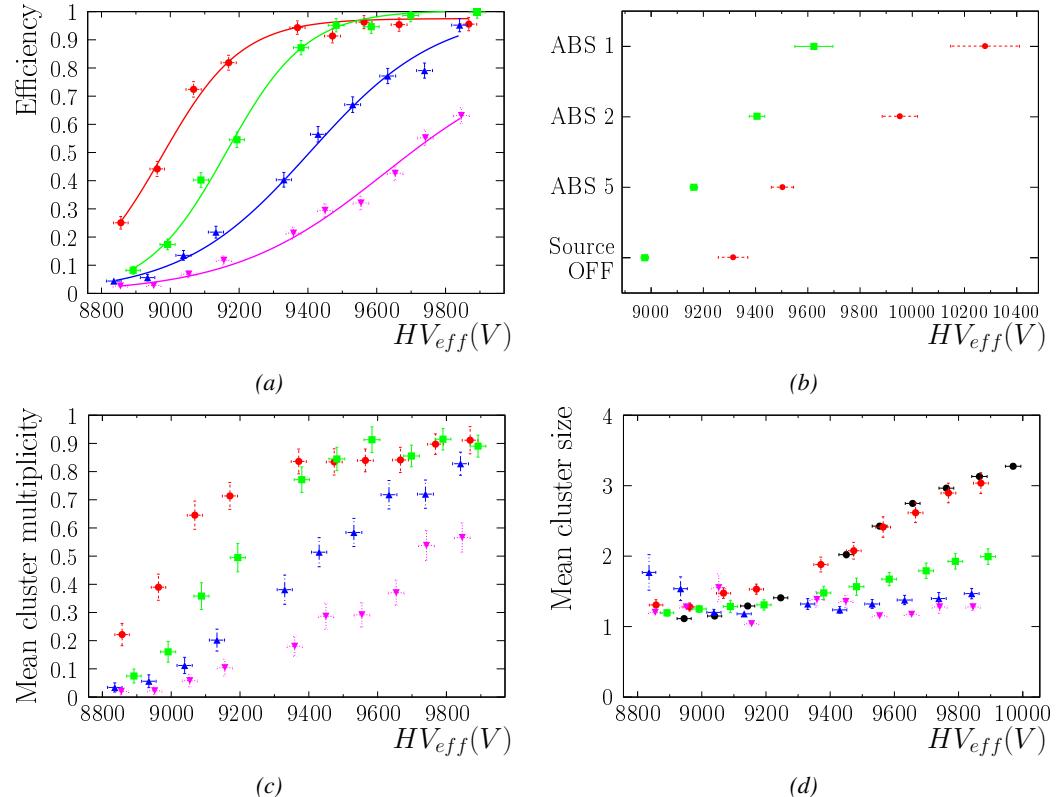

Figure 5.17

2241 5.4 Longevity tests at GIF++

2242 Longevity studies imply a monitoring of the performance of the detectors probed using a high inten-
2243 sity muon beam in a irradiated environment by periodically measuring their rate capability, the dark
2244 current running through them and the bulk resistivity of the Bakelite composing their electrodes.
2245 GIF++, with its very intense ^{137}Cs source, provides the perfect environment to perform such kind
2246 of tests. Assuming a maximum acceleration factor of 3, it is expected to accumulate the equivalent
2247 charge in 1.7 years.

2248 As the maximum background is found in the endcap, the choice naturally was made to focus the
2249 GIF++ longevity studies on endcap chambers. Most of the RPC system was installed in 2007. Nev-
2250 ertheless, the large chambers in the fourth endcap (RE4/2 and RE4/3) have been installed during
2251 LS1 in 2014. The Bakelite of these two different productions having different properties, four spare
2252 chambers of the present system were selected, two RE2,3/2 spares and two RE4/2 spares. Having
2253 two chambers of each type allows to always keep one of them non irradiated as reference, the per-
2254 formance evolution of the irradiated chamber being then compared through time to the performance
2255 of the non irradiated one.

2256 The performance of the detectors under different level of irradiation is measured periodically dur-
2257 ing dedicated test beam periods using the H4 muon beam. In between these test beam periods, the
2258 two RE2,3/2 and RE4/2 chambers selected for this study are irradiated by the ^{137}Cs source in order
2259 to accumulate charge and the gamma background is monitored, as well as the currents. The two
2260 remaining chambers are kept non-irradiated as reference detectors. Due to the limited gas flow in
2261 GIF++, the RE4 chamber remained non-irradiated until end of November 2016 where a new mass
2262 flow controller has been installed allowing for bigger volumes of gas to flow in the system.

2263 Figures 5.18 and 5.19 give us for different test beam periods, and thus for increasing integrated
2264 charge through time, a comparison of the maximum efficiency, obtained using a sigmoid-like func-
2265 tion, and of the working point of both irradiated and non irradiated chambers [50]. No aging is yet
2266 to see from this data, the shifts in γ rate per unit area in between irradiated and non irradiated detec-
2267 tors and RE2 and RE4 types being easily explained by a difference of sensitivity due to the various
2268 Bakelite resistivities of the HPL electrodes used for the electrode production.

2269 Collecting performance data at each test beam period allows us to extrapolate the maximum effi-
2270 ciency for a background hit rate of 300 Hz/cm² corresponding to the expected HL-LHC conditions.
2271 Aging effects could emerge from a loss of efficiency with increasing integrated charge over time,
2272 thus Figure 5.20 helps us understand such degradation of the performance of irradiated detectors in
2273 comparison with non irradiated ones. The final answer for an eventual loss of efficiency is given in
2274 Figure 5.21 by comparing for both irradiated and non irradiated detectors the efficiency sigmoids
2275 before and after the longevity study. Moreover, to complete the performance information, the Bake-
2276 lite resistivity is regularly measured thanks to Ag scans (Figure 5.22) and the noise rate is monitored
2277 weekly during irradiation periods (Figure 5.23). At the end of 2016, no signs of aging were observed
2278 and further investigation is needed to get closer to the final integrated charge requirements proposed
2279 for the longevity study of the present CMS RPC sub-system.

2280

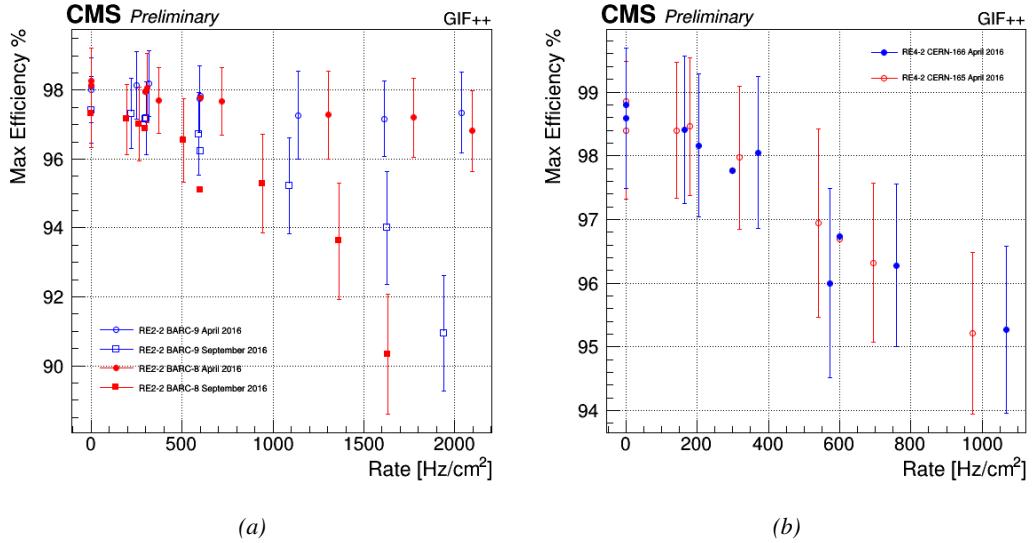

Figure 5.18: Evolution of the maximum efficiency for RE2 (5.18a) and RE4 (5.18b) chambers with increasing extrapolated γ rate per unit area at working point. Both irradiated (blue) and non irradiated (red) chambers are shown.

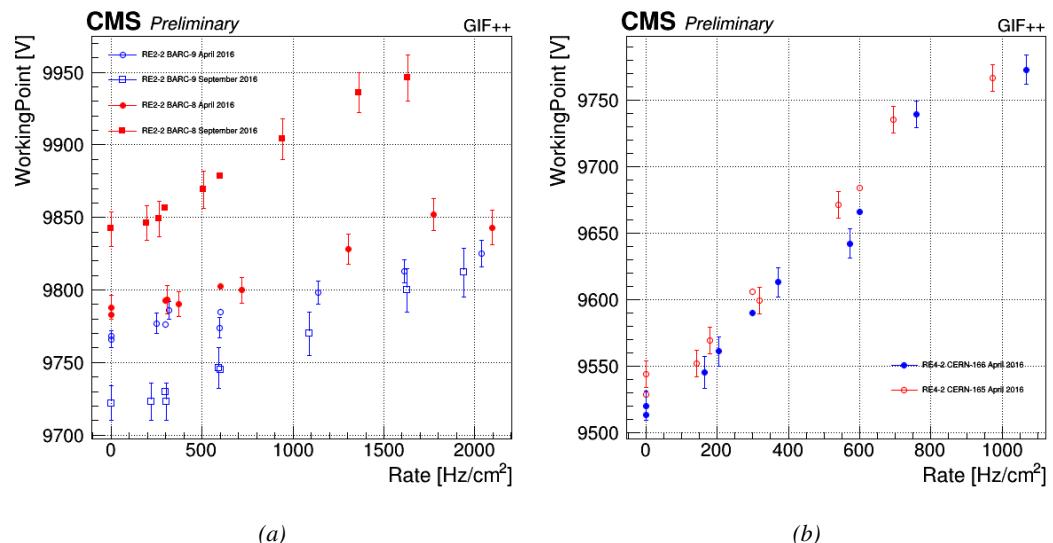

Figure 5.19: Evolution of the working point for RE2 (5.19a) and RE4 (5.19b) with increasing extrapolated γ rate per unit area at working point. Both irradiated (blue) and non irradiated (red) chambers are shown.

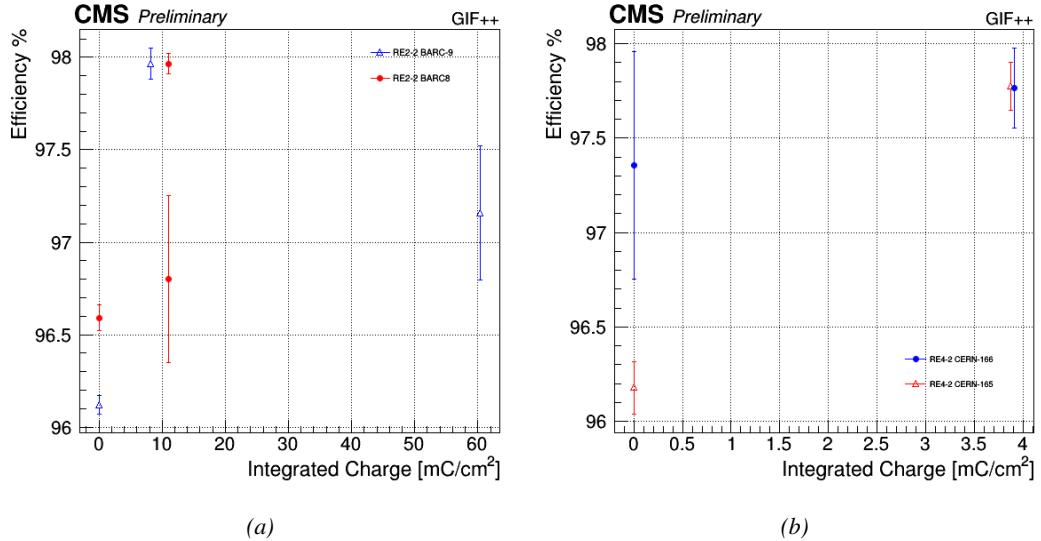

Figure 5.20: Evolution of the maximum efficiency at HL-LHC conditions, i.e. a background hit rate per unit area of 300 Hz/cm², with increasing integrated charge for RE2 (5.20a) and RE4 (5.20b) detectors. Both irradiated (blue) and non irradiated (red) chambers are shown. The integrated charge for non irradiated detectors is recorded during test beam periods and stays small with respect to the charge accumulated in irradiated chambers.

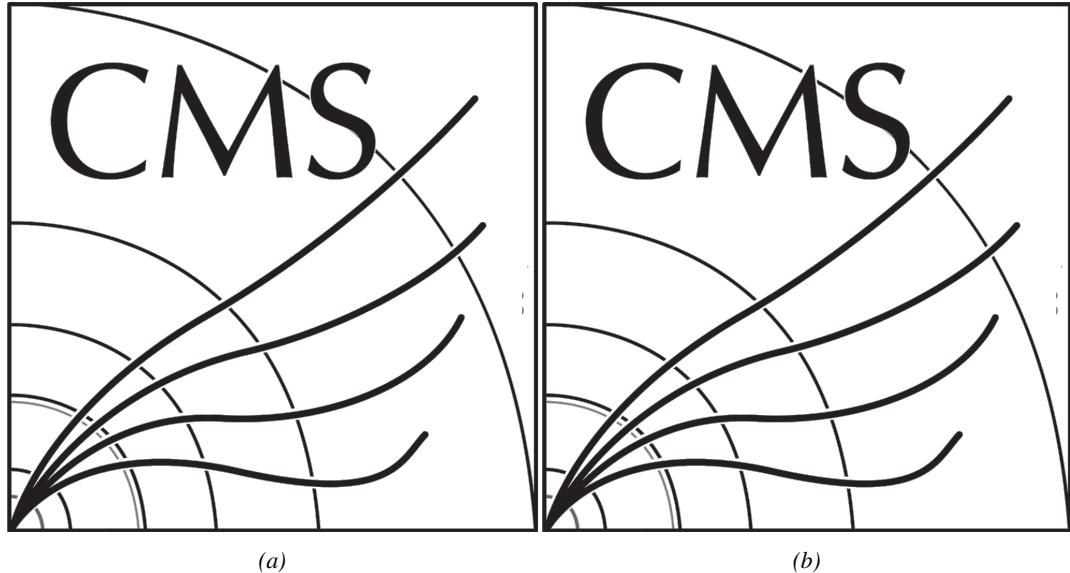

Figure 5.21: Comparison of the efficiency sigmoid before (triangles) and after (circles) irradiation for RE2 (5.21a) and RE4 (5.21b) detectors. Both irradiated (blue) and non irradiated (red) chambers are shown.

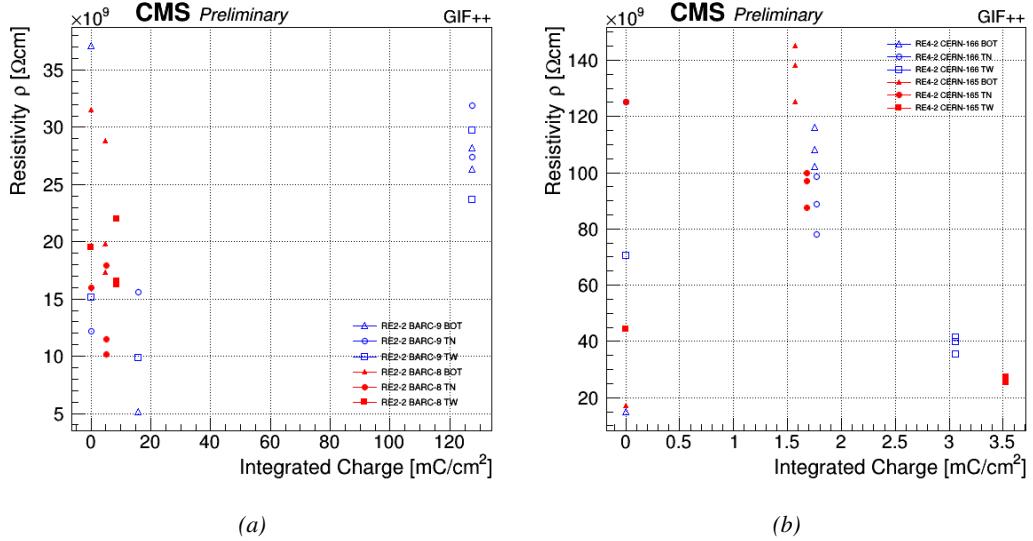

Figure 5.22: Evolution of the Bakelite resistivity for RE2 (5.22a) and RE4 (5.22b) detectors. Both irradiated (blue) and non-irradiated (red) chambers are shown.

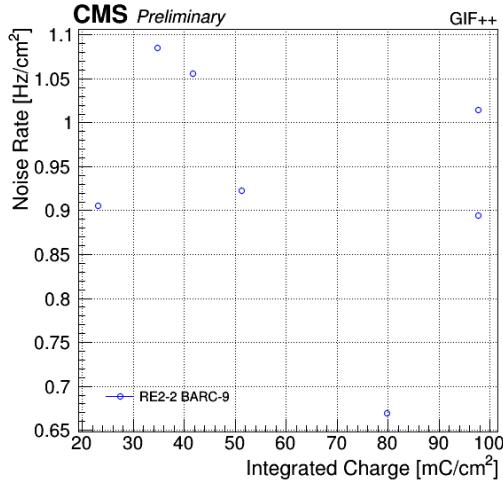

Figure 5.23: Evolution of the noise rate per unit area for the irradiated chamber RE2-2-BARC-9 only.

5.4.1 Description of the Data Acquisition

For the longevity studies, four spare chambers of the present system are used. Two spare RPCs of the RE2,3 stations as well as two spare RPCs from the new RE4 stations have been mounted in a Trolley. Six RE4 gaps are also placed in the trolley. The trolley is placed inside the GIFT++ in the upstream region of the bunker, taking the cesium source as a reference. The trolley is oriented for the detection surface of the chambers to be orthogonal to the beam line. The system can be moved along the orthogonal plane in order to have the beam in all η -partitions. For the aging the trolley is

2288 moved outside the beam line and is placed in a distance of 5.2 m to the source, which irradiates the
 2289 bunker using an attenuation filter of 2.2 which corresponds to a fluence of 10^7 gamma/cm^2 .

2290 During GIF++ operation, the data collected can be divided into different categories as several
 2291 parameters are monitored in addition to the usual RPC performance data. On one hand, to know
 2292 the performance of a chamber, it is need to measure its efficiency and to know the background
 2293 conditions in which it is operated. To do this, the hit signals from the chamber are recorded and
 2294 stored in a ROOT file via a Data Acquisition (DAQ) software. On the other hand, it is also very
 2295 important to monitor parameters such as environmental pressure and temperature, gas temperature
 2296 and humidity, RPC HV, LV, and currents, or even source and beam status. This is done through the
 2297 GIF++ web Detector Control Software (DCS) that stores this information in a database.

2298 Two different types of tests are conducted on RPCs via the DAQ. Indeed, the performance of the
 2299 detectors is measured periodically during dedicated test beam periods using the H4 muon beam. In
 2300 between these test beam periods, when the beam is not available, the chambers are irradiated by the
 2301 ^{137}Cs in order to accumulate deposited charge and the gamma background is measured.

2302 RPCs under test are connected through LVDS cables to V1190A Time-to-Digital Converter
 2303 (TDC) modules manufactured by CAEN. These modules, located in the rack area outside of the
 2304 bunker, get the logic signals sent by the chambers and save them into their buffers. Due to the
 2305 limited size of the buffers, the collected data is regularly erased and replaced. A trigger signal is
 2306 needed for the TDC modules to send the useful data to the DAQ computer via a V1718 CAEN USB
 2307 communication module.

2308 In the case of performance test, the trigger signal used for data acquisition is generated by the
 2309 coincidence of three scintillators. A first one is placed upstream outside of the bunker, a second one
 2310 is placed downstream outside of the bunker, while a third one is placed in front of the trolley, close by
 2311 the chambers. Every time a trigger is sent to the TDCs, i.e. every time a muon is detected, knowing
 2312 the time delay in between the trigger and the RPC signals, signals located in the right time window
 2313 are extracted from the buffers and saved for later analysis. Signals are taken in a time window of
 2314 400 ns centered on the muon peak (here we could show a time spectrum). On the other hand, in the
 2315 case of background rate measurement, the trigger signal needs to be "random" not to measure muons
 2316 but to look at gamma background. A trigger pulse is continuously generated at a rate of 300 Hz using
 2317 a dual timer. To integrate an as great as possible time, all signals contained within a time window of
 2318 10us prior to the random trigger signal are extracted form the buffers and saved for further analysis
 2319 (here another time spectrum to illustrate could be useful, maybe even place both spectrum together
 2320 as a single Figure).

2321 The signals sent to the TDCs correspond to hit collections in the RPCs. When a particle hits
 2322 a RPC, it induce a signal in the pickup strips of the RPC readout. If this signal is higher than the
 2323 detection threshold, a LVDS signal is sent to the TDCs. The data is then organised into 4 branches
 2324 keeping track of the event number, the hit multiplicity for the whole setup, and the time and channel
 2325 profile of the hits in the TDCs.

2326 **5.4.2 RPC current, environmental and operation parameter monitoring**

2327 In order to take into account the variation of pressure and temperature between different data taking
 2328 periods the applied voltage is corrected following the relationship :

$$2329 \quad HV_{eff} = HV_{app} \times \left(0.2 + 0.8 \cdot \frac{P_0}{P} \times \frac{T}{T_0} \right) \quad (5.10)$$

2329 where T_0 (=293 K) and P_0 (=990 mbar) are the reference values.

2330 **5.4.3 Measurement procedure**

2331 Insert a short description of the online tools (DAQ, DCS, DQM).

2332 Insert a short description of the offline tools : tracking and efficiency algorithm.

2333 Identify long term aging effects we are monitoring the rates per strip.

2346

2347

A data acquisition software for CAEN VME TDCs

2348

2349 Certifying detectors in the perspective of HL-LHC required to develop tools for the GIF++ experiment.
2350 Among them was the C++ Data Acquisition (DAQ) software that allows to make the communications
2351 in between a computer and TDC modules in order to retrieve the RPC data [63]. In this
2352 appendix, details about this software, as of how the software was written, how it functions and how
2353 it can be exported to another similar setup, will be given.

2354 A.1 GIF++ DAQ file tree

2355 GIF++ DAQ source code is fully available on github at https://github.com/afagot/GIF_DAQ. The software requires 3 non-optional dependencies:

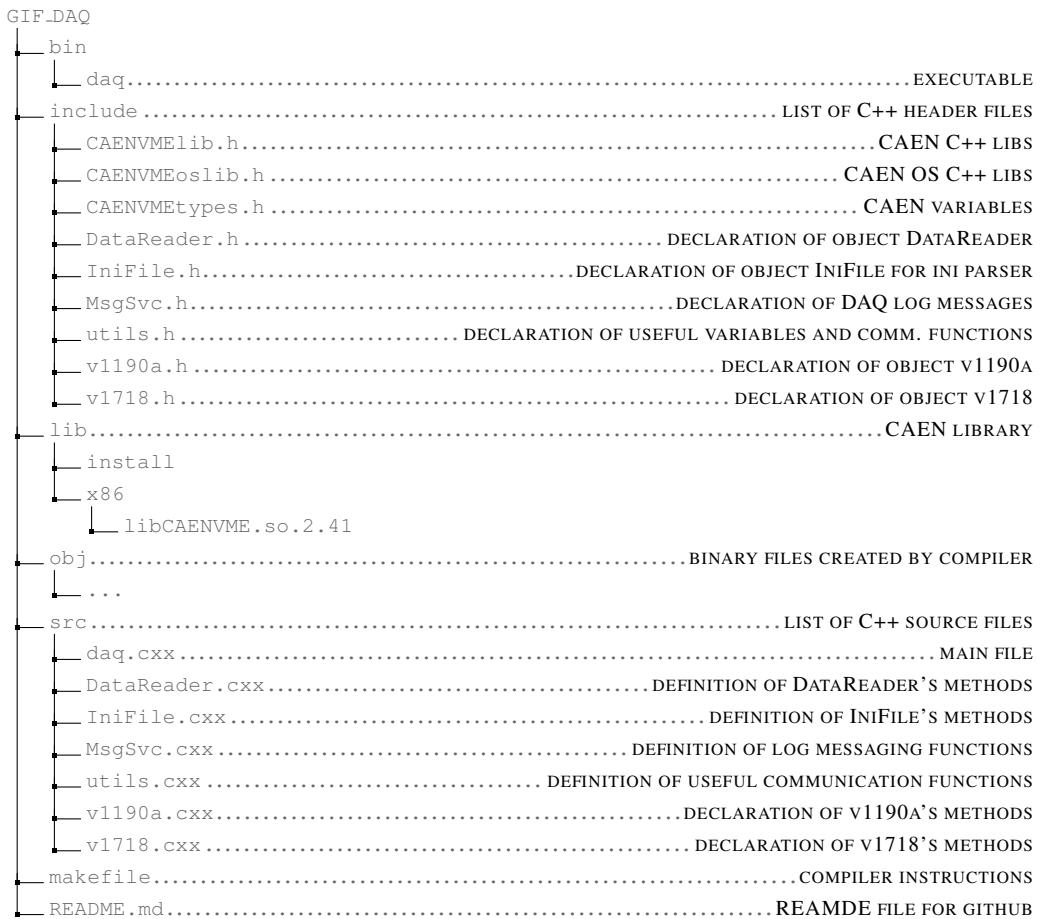

- 2357 • CAEN USB Driver, to mount the VME hardware,
2358 • CAEN VME Library, to communicate with the VME hardware, and
2359 • ROOT, to organize the collected data into a TTree.

2360 The CAEN VME library will not be packaged by distributions and will need to be installed man-
2361 ually. To compile the GIF++ DAQ project via a terminal, from the DAQ folder use the command:

2362 make

2364 The source code tree is provided below along with comments to give an overview of the files' con-
2365 tent. The different objects created for this project (`v1718`, `v1190a`, `IniFile` & `DataReader`) will be
2366 described in details in the following sections.

2367

2368 A.2 Usage of the DAQ

2369 GIF++ DAQ, as used in GIF++, is not a standalone software. Indeed, the system being more complexe,
 2370 the DAQ only is a sub-layer of the software architecture developped to control and monitor
 2371 the RPCs that are placed into the bunker for performance study in an irradiated environment. The top
 2372 layer of GIF++ is a Web Detector Control System (webDCS) application. The DAQ is only called
 2373 by the webDCS when data needs to be acquired. The webDCS operates the DAQ through command
 2374 line. To start the DAQ, the webDCS calls:

2375

2376 bin/daq /path/to/the/log/file/in/the/output/data/folder

2377 where /path/to/the/log/file/in/the/output/data/folder is the only argument required. This
 2378 log file is important for the webDCS as this file contains all the content of the communication of the
 2379 webDCS and the different systems monitored by the webDCS. Its content is constantly displayed
 2380 during data taking for the users to be able to follow the operations. The communication messages
 2381 are normally sent to the webDCS log file via the functions declared in file MsgSvc.h, typically
 2382 MSG_INFO(string message).

2383

2384 A.3 Description of the readout setup

2385 The CMS RPC setup at GIF++ counts 5 V1190A Time-to-Digital Converter (TDC) manufactured
 2386 by CAEN [64]. V1190A are VME units accepting 128 independent Multi-Hit/Multi-Event TDC
 2387 channels whose signals are treated by 4 100 ps high performance TDC chips developed by CERN
 2388 / ECP-MIC Division. The communication between the computer and the TDCs to transfer data is
 2389 done via a V1718 VME master module also manufactured by CAEN and operated from a USB
 2390 port [65]. These VME modules are all hosted into a 6U VME 6021 powered crate manufactured by
 2391 W-Ie-Ne-R than can accommodate up to 21 VME bus cards [66]. These 3 components of the DAQ
 2392 setup are shown in Figure A.1.

2393

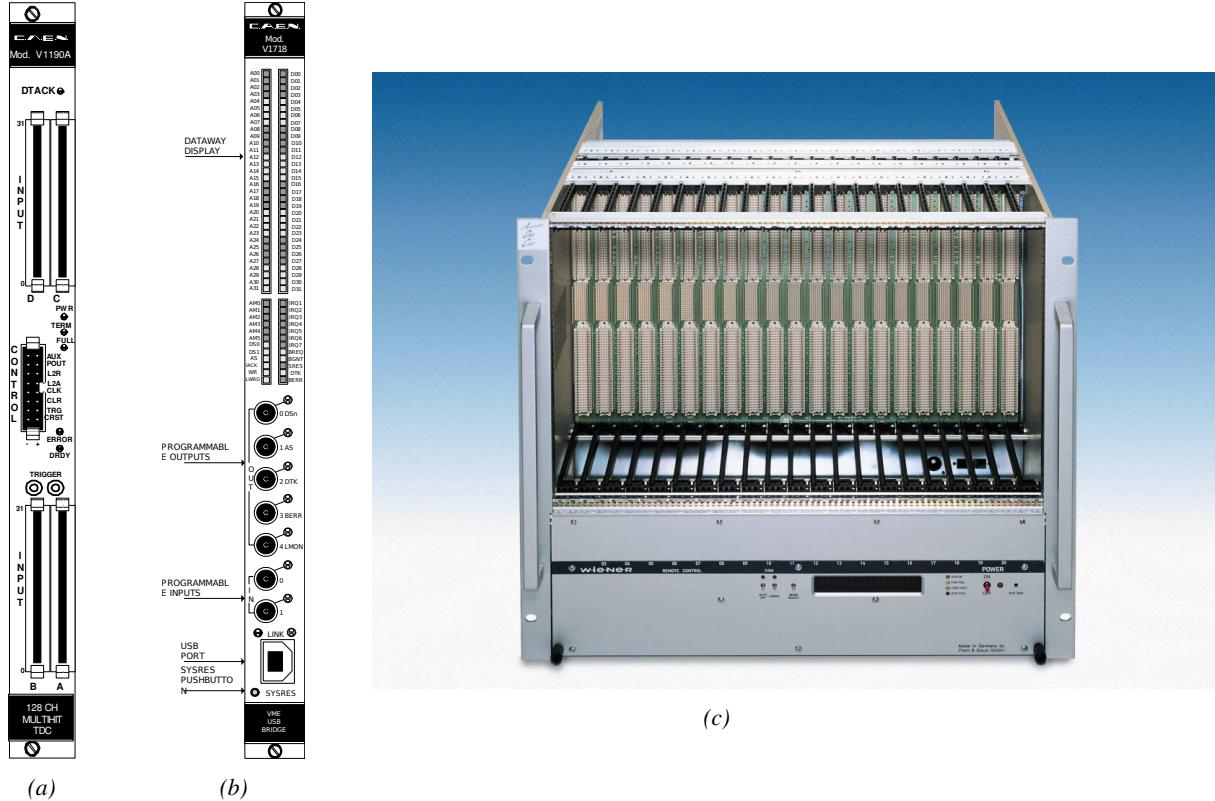

Figure A.1: (A.1a) View of the front panel of a V1190A TDC module [64]. (A.1b) View of the front panel of a V1718 Bridge module [65]. (A.1c) View of the front panel of a 6U 6021 VME crate [66].

2394

A.4 Data read-out

2395 To efficiently perform a data readout algorithm, C++ objects to handle the VME modules (TDCs
 2396 and VME bridge) have been created along with objects to store data and read the configuration file

2397 that comes as an input of the DAQ software.

2398

2399 A.4.1 V1190A TDCs

2400 The DAQ used at GIF takes profit of the *Trigger Matching Mode* offered by V1190A modules.
 2401 This setting is enabled through the method `v1190a::SetTrigMatching (int ntdcs)` where `ntdcs`
 2402 is the total number of TDCs in the setup this setting needs to be enabled for (Source Code A.1). A
 2403 trigger matching is performed in between a trigger time tag, a trigger signal sent into the TRIGGER
 2404 input of the TDC visible on Figure A.1a, and the channel time measurements, signals recorded from
 2405 the detectors under test in our case. Control over this data acquisition mode, explained through
 2406 Figure A.2, is offered via 4 programmable parameters:

- 2407 • **match window:** the matching between a trigger and a hit is done within a programmable time
 2408 window. This is set via the method

2409 `void v1190a::SetTrigWindowWidth(Uint windowHeight, int ntdcs)`

- 2410 • **window offset:** temporal distance between the trigger tag and the start of the trigger matching
 2411 window. This is set via the method

2412 `void v1190a::SetTrigWindowWidth(Uint windowHeight, int ntdcs)`

- 2413 • **extra search margin:** an extended time window is used to ensure that all matching hits are
 2414 found. This is set via the method

2415 `void v1190a::SetTrigSearchMargin(Uint searchMargin, int ntdcs)`

- 2416 • **reject margin:** older hits are automatically rejected to prevent buffer overflows and to speed
 2417 up the search time. This is set via the method

2418 `void v1190a::SetTrigRejectionMargin(Uint rejectMargin, int ntdcs)`

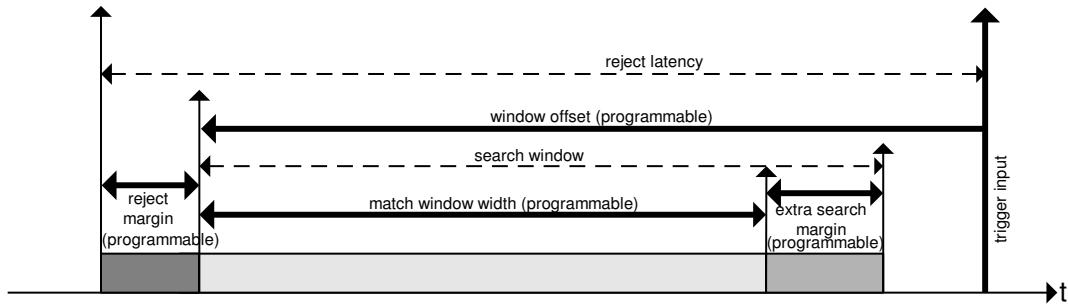

Figure A.2: Module V1190A Trigger Matching Mode timing diagram [64].

2419 Each of these 4 parameters are given in number of clocks, 1 clock being 25 ns long. It is easy to
 2420 understand at this level that there are 3 possible functioning settings:

- 2421 • **1:** the match window is entirely contained after the trigger signal,

- 2422 • **2:** the match window overlaps the trigger signal, or

- 2423 • **3:** the match window is entirely contained before the trigger signal as displayed on Figure A.2.

2424 In both the first and second cases, the sum of the window width and of the offset can be set to
2425 a maximum of 40 clocks, which corresponds to 1 μ s. Evidently, the offset can be negative, allowing
2426 for a longer match window, with the constraint of having the window ending at most 1 μ s after the
2427 trigger signal. In the third case, the maximum negative offset allowed is of 2048 clocks (12 bit) cor-
2428 responding to 51.2 μ s, the match window being strictly smaller than the offset. In the case of GIF++,
2429 the choice has been made to use this last setting by delaying the trigger signal. During the studies
2430 performed in GIF++, both the efficiency of the RPCs, probed using a muon beam, and the noise or
2431 gamma background rate are monitored. The extra search and reject margins are left unused.
2432 To probe the efficiency of RPC detectors, the trigger time tag is provided by the coïncidence of
2433 scintillators when a bunch of muons passes through GIF++ area is used to trigger the data acquisi-
2434 tion. For this measurement, it is useful to reduce the match window width only to contain the muon
2435 information. Indeed, the delay in between a trigger signal and the detection of the corresponding
2436 muon in the RPC being very contant (typically a few tens of ns due to jitter and cable length), the
2437 muon signals are very localised in time. Thus, due to a delay of approximalety 325 ns in between
2438 the muons and the trigger, the settings where chosen to have a window width of 24 clocks (600 ns)
2439 centered on the muon peak thanks to a negative offset of 29 clocks (725 ns).
2440 On the otherhand, monitoring the rates don't require for the DAQ to look at a specific time window.
2441 It is important to integrate enough time to have a robust measurement of the rate as the number of
2442 hits per time unit. The triggerring signal is provided by a pulse generator at a frequency of 300 Hz
2443 to ensure that the data taking occurs in a random way, with respect to beam physics, to probe only
2444 the irradiation spectrum on the detectors. The match window is set to 400 clocks (10 μ s) and the
2445 negative offset to 401 clocks as it needs to exceed the value of the match window.

        void SwitchChannels(IniFile *inifile,int ntdcs);
        void SetIRQ(Data32 level, Data32 count,int ntdcs);
        void SetBlockTransferMode(Data16 mode,int ntdcs);
        void Set(IniFile *inifile,int ntdcs);
        void CheckStatus(CVErrorCodes status) const;
        int ReadBlockD32(Uint tdc, const Data16 address,
                           Data32 *data, const Uint words, bool ignore_berr);
        Uint Read(RAWData *DataList,int ntdcs);
};

2447

```

2448 *Source Code A.1: Description of C++ object v1190a.*

2449 The v1190a object, defined in the DAQ software as in Source Code A.1, offers the possibility to
 2450 concatenate all TDCs in the readout setup into a single object containing a list of hardware addresses
 2451 (addresses to access the TDCs' buffer through the VME crate) and each constructor and method acts
 2452 on the list of TDCs.

2453

2454 A.4.2 DataReader

2455 Enabled thanks to v1190a::SetBlockTransferMode(Data16 mode, **int** ntdcs), the data transfer
 2456 is done via Block Transfer (BLT). Using BLT allows to tranfer a fixed number of events called a
 2457 *block*. This is used together with an Almost Full Level (AFL) of the TDCs' output buffers, defined

2458 through `v1190a::SetIRQ(Data32 level, Data32 count, int ntdcs)`. This AFL gives the maximum amount of 32735 words (16 bits, corresponding to the depth of a TDC output buffer) that can
 2459 be written in a buffer before an Interrupt Request (IRQ) is generated and seen by the VME Bridge,
 2460 stopping the data acquisition to transfer the content of each TDC buffers before resuming. For each
 2461 trigger, 6 words or more are written into the TDC buffer:

- 2463 • a **global header** providing information of the event number since the beginning of the data
 acquisition,
- 2465 • a **TDC header**,
- 2466 • the **TDC data** (*if any*), 1 for each hit recorded during the event, providing the channel and the
 time stamp associated to the hit,
- 2468 • a **TDC error** providing error flags,
- 2469 • a **TDC trailer**,
- 2470 • a **global trigger time tag** that provides the absolute trigger time relatively to the last reset,
 and
- 2472 • a **global trailer** providing the total word count in the event.

2473 As previously described in Section ??, CMS RPC FEEs provide us with 100 ns long LVDS output
 2474 signals that are injected into the TDCs' input. Any avalanche signal that gives a signal above the
 2475 FEEs threshold is thus recorded by the TDCs as a hit within the match window. Each hit is assigned
 2476 to a specific TDC channel with a time stamp, with a precision of 100 ps. The reference time, $t_0 = 0$,
 2477 is provided by the beginning of the match window. Thus for each trigger, coming from a scintillator
 2478 coïncidence or the pulse generator, a list of hits is stored into the TDCs' buffers and will then be
 2479 transferred into a ROOT Tree.

2480 When the BLT is used, it is easy to understand that the maximum number of words that have
 2481 been set as ALF will not be a finite number of events or, at least, the number of events that would
 2482 be recorded into the TDC buffers will not be a multiple of the block size. In the last BLT cycle to
 2483 transfer data, the number of events to transfer will most probably be lower than the block size. In that
 2484 case, the TDC can add fillers at the end of the block but this option requires to send more data to the
 2485 computer and is thus a little slower. Another solution is to finish the transfer after the last event by
 2486 sending a bus error that states that the BLT reached the last event in the pile. This method has been
 2487 chosen in GIF++.

2489 Due to irradiation, an event in GIF++ can count up to 300 words per TDC. A limit of 4096 words
 2490 (12 bits) has been set to generate IRQ which represent from 14 to almost 700 events depending on
 2491 the average of hits collected per event. Then the block size has been set to 100 events with enabled
 2492 bus errors. When an AFL is reached for one of the TDCs, the VME bridge stops the acquisition by
 2493 sending a BUSY signal.

2495

2496 The data is then transferred one TDC at a time into a structure called `RAWData` (Source Code A.2).

```
2497
2498 struct RAWData{
2499     vector<int>           *EventList;
2500     vector<int>           *NHitsList;
2501     vector<int>           *QFlagList;
2502     vector<vector<int>>   *Channellist;
2503     vector<vector<float>>  *TimeStampList;
2504 };
2505
```

2506 *Source Code A.2: Description of data holding C++ structure `RAWData`.*

2507 In order to organize the data transfer and the data storage, an object called `DataReader` was
 2508 created (Source Code A.3). On one hand, it has `v1718` and `v1190a` objects as private members for
 2509 communication purposes, such as VME modules settings via the configuration file `*iniFile` or data
 2510 read-out through `v1190a::Read()` and on the other hand, it contains the structure `RAWData` that allows
 2511 to organise the data in vectors reproducing the tree structure of a ROOT file.

```
2512
2513 class DataReader
2514 {
2515     private:
2516     bool      StopFlag;
2517     IniFile  *iniFile;
2518     Data32    MaxTriggers;
2519     v1718    *VME;
2520     int       nTDCs;
2521     v1190a   *TDCs;
2522     RAWData  TDCData;
2523
2524     public:
2525     DataReader();
2526     virtual ~DataReader();
2527     void      SetIniFile(string inifilename);
2528     void      SetMaxTriggers();
2529     Data32    GetMaxTriggers();
2530     void      SetVME();
2531     void      SetTDC();
2532     int       GetQFlag(Uint it);
2533     void      Init(string inifilename);
2534     void      FlushBuffer();
2535     void      Update();
2536     string   GetFileName();
2537     void      WriteRunRegistry(string filename);
2538     void      Run();
2539 };
2540
```

2541 *Source Code A.3: Description of C++ object `DataReader`.*

2542 Each event is transferred from `TDCData` and saved into branches of a ROOT `TTree` as 3 integers
 2543 that represent the event ID (`EventCount`), the number of hits read from the TDCs (`nHits`), and the
 2544 quality flag that provides information for any problem in the data transfer (`qflag`), and 2 lists of
 2545 `nHits` elements containing the fired TDC channels (`TDCCh`) and their respective time stamps (`TDCTS`),
 2546 as presented in Source Code A.4. The ROOT file file is named using information contained into
 2547 the configuration file, presented in section A.5.2. The needed information is extracted using method
 2548 `DataReader::GetFileName()` and allow to build the output filename format `ScanXXXXXX_HVX_DAQ.root`

2515 where ScanXXXXXX is a 6 digit number representing the scan number into GIFT++ database and HVX
 2516 the HV step within the scan that can be more than a single digit. An example of ROOT data file is
 2517 provided with Figure A.3.

```
2518
RAWData TDCData;
TFile *outputFile = new TFile(outputFileName.c_str(),"recreate");
TTree *RAWDataTree = new TTree("RAWData","RAWData");

int EventCount = -9;
int nHits = -8;
int qflag = -7;
vector<int> TDCCh;
vector<float> TDCTS;

RAWDataTree->Branch("EventNumber",&EventCount, "EventNumber/I");
RAWDataTree->Branch("number_of_hits",&nHits,"number_of_hits/I");
RAWDataTree->Branch("Quality_flag",&qflag,"Quality_flag/I");
RAWDataTree->Branch("TDC_channel",&TDCCh);
RAWDataTree->Branch("TDC_TimeStamp",&TDCTS);

2519
//...
//Here read the TDC data using v1190a::Read() and place it into
//TDCData for as long as you didn't collect the requested amount
//of data.
//...

for(Uint i=0; i<TDCData.EventList->size(); i++){
    EventCount = TDCData.EventList->at(i);
    nHits = TDCData.NHitsList->at(i);
    qflag = TDCData.QFlagList->at(i);
    TDCCh = TDCData.ChannelList->at(i);
    TDCTS = TDCData.TimeStampList->at(i);
    RAWDataTree->Fill();
}
```

2520 *Source Code A.4: Highlight of the data transfer and organisation within DataReader::Run() after the data has been collected into TDCData.*

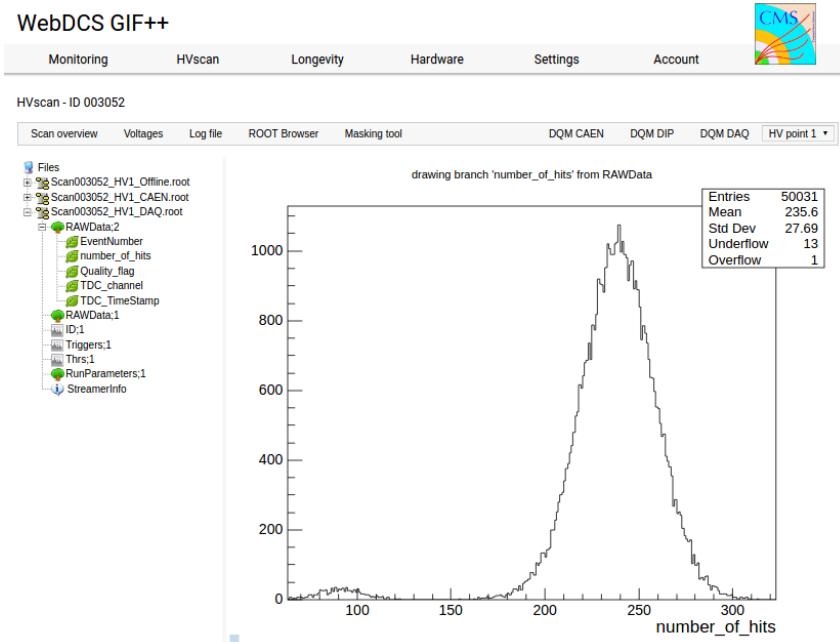

Figure A.3: Structure of the ROOT output file generated by the DAQ. The 5 branches (EventNumber, number_of_hits, Quality_flag, TDC_channel and TDC_TimeStamp) are visible on the left panel of the ROOT browser. On the right panel is visible the histogram corresponding to the variable nHits. In this specific example, there were approximately 50k events recorded to measure the gamma irradiation rate on the detectors. Each event is stored as a single entry in the TTree.

A.4.3 Data quality flag

Among the parameters that are recorded for each event, the quality flag, defined in Source Code A.5, is determined on the fly by checking the data recorded by every single TDC. From method `v1190a::Read()`, it can be understood that the content of each TDC buffer is readout one TDC at a time. Entries are created in the data list for the first TDC and then, when the second buffer is readout, events corresponding to entries that have already been created to store data for the previous TDC are added to the existing list element. On the contrary, when an event entry has not been yet created in the data list, a new entry is created.

```
2521
2522 typedef enum _QualityFlag {
2523     GOOD      = 1,
2524     CORRUPTED = 0
2525 } QualityFlag;
```

2531 *Source Code A.5: Definition of the quality flag `enum`.*

2532 It is possible that each TDC buffer contains a different number of events. In cases where the first
2533 element in the buffer list is an event for corresponds to a new entry, the difference in between the
2534 entry from the buffer and the last entry in the data list is recorded and checked. If it is greater than 1,
2535 what should never be the case, the quality flag is set to CORRUPTED for this TDC and an empty entry
2536 is created in the place of the missing ones. Missing entries are believe to be the result of a bad hold

2537 on the TDC buffers at the moment of the readout. Indeed, the software hold is effective only on 1
 2538 TDC at a time and no solution as been found yet to completely block the writting in the buffers when
 2539 an IRQ is received.

2540 At the end of each BLT cycle, the ID of the last entry stored for each TDC buffer is not recorded.
 2541 When starting the next cycle, if the first entry in the pile corresponds to an event already existing
 2542 in the list, the readout will start from this list element and will not be able to check the difference
 2543 in between this entry's ID and the one of the last entry that was recorded for this TDC buffer in
 2544 the previous cycle. In the case events were missing, the flag stays at its initial value of 0, which is
 2545 similar to CORRUPTED and it is assumed that then this TDC will not contribute to `number_of_hits`,
 2546 `TDC_channel` or `TDC_TimeStamp`.

2547 Finally, since there will be 1 `RAWData` entry per TDC for each event (meaning `nTDCs` entries,
 2548 referring to `DataReader` private attribute), the individual flags of each TDC will be added together.
 2549 The final format is an integer composed `nTDCs` digits where each digit is the flag of a specific TDC.
 2550 This is constructed using powers of 10 like follows:

```
2551 TDC 0: QFlag = 100 × _QualityFlag
2552 TDC 1: QFlag = 101 × _QualityFlag
2553 ...
2554 TDC N: QFlag = 10N × _QualityFlag
```

2555 and the final flag to be with N digits:

```
2556 QFlag = n....3210
```

2557 each digit being 1 or 0. Below is given an example with a 4 TDCs setup.

2558 If all TDCs were good : `QFlag = 1111`,

2559 but if TDC 2 was corrupted : `QFlag = 1011`.

2560 When data taking is over and the data contained in the dynamical `RAWData` structure is transferred
 2561 to the ROOT file, all the 0s are changed into 2s by calling the method `DataReader::GetQFlag()`.
 2562 This will help translating the flag without knowing the number of TDCs beforehand. Indeed, a flag
 2563 111 could be due to a 3 TDC setup with 3 good individual TDC flags or to a more than 3 TDC setup
 2564 with TDCs those ID is greater than 2 being CORRUPTED, thus giving a 0.

2565 The quality flag has been introduced quite late, in October 2017 only, to the list of GIFT++ DAQ
 2566 parameters to be recorded into the output ROOT file. Before this addition, the missing data, corrupting
 2567 the quality for the offline analysis, was contributing to artificially fill data with lower multiplicity.
 2568 Looking at `TBranch number_of_hits` provides an information about the data of the full GIFT++
 2569 setup. When a TDC is not able to transfer data for a specific event, the effect is a reduction of the
 2570 total number of hits recorded in the full setup, this is what can be seen from Figure A.4. After offline
 2571 reconstruction detector by detector, the effect of missing events can be seen in the artificially filled
 2572 bin at multiplicity 0 shown in Figure A.5. Nonetheless, for data with high irradiation levels, as it is
 2573 the case for Figure A.5a, discarding the fake multiplicity 0 data can be done easily during the offline
 2574 analysis. At lower radiation, the missing events contribution becomes more problematic as the mul-
 2575 tiplicity distribution overlaps the multiplicity 0 and that in the same time the proportion of missing

2576 events decreases. Attempts to fit the distribution with a Poisson or skew distribution function were
 2577 not conclusive and this very problem has been at the origin of the quality flag that allows to give a
 2578 non ambiguous information about each event quality.

2579

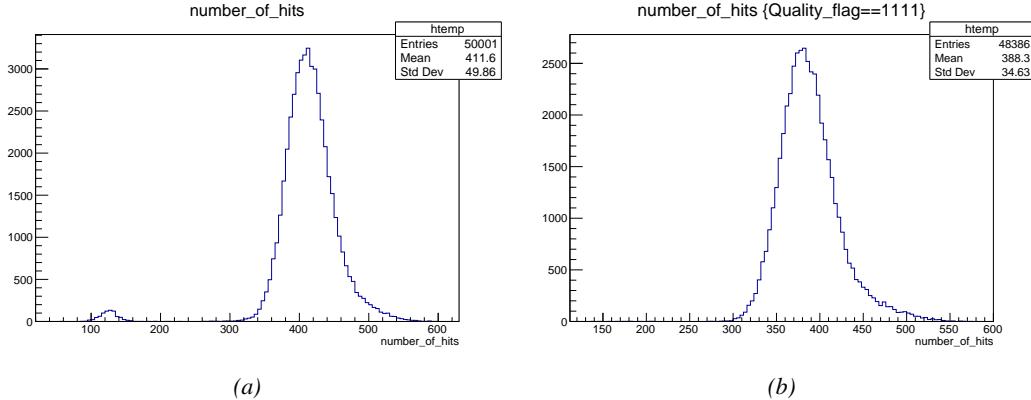

Figure A.4: The effect of the quality flag is explained by presenting the content of TBranch `number_of_hits` of a data file without `Quality_flag` in Figure A.4a and the content of the same TBranch for data corresponding to a `Quality_flag` where all TDCs were labelled as `GOOD` in Figure A.4b taken with similar conditions. It can be noted that the number of entries in Figure A.4b is slightly lower than in Figure A.4a due to the excluded events.

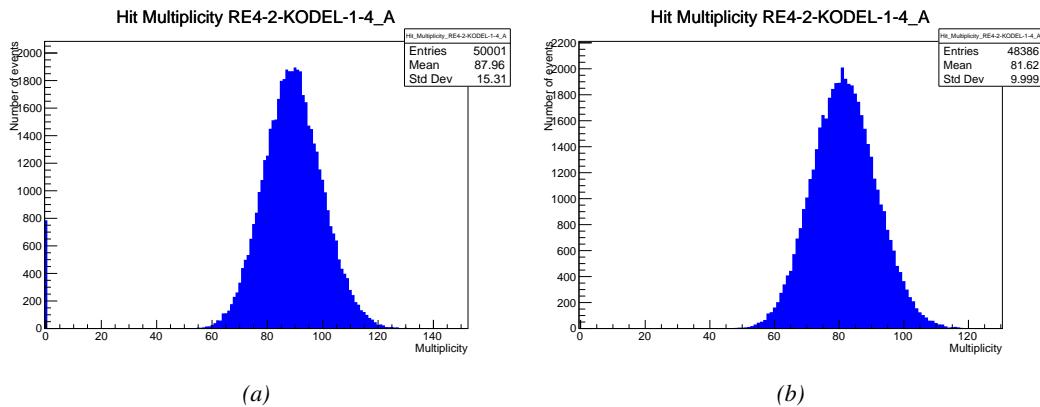

Figure A.5: Using the same data as previously showed in Figure A.4, the effect of the quality flag is explained by presenting the reconstructed hit multiplicity of a data file without `Quality_flag` in Figure A.5a and the reconstructed content of the same RPC partition for data corresponding to a `Quality_flag` where all TDCs were labelled as `GOOD` in Figure A.5b taken with similar conditions. The artificial high content of bin 0 is completely suppressed.

A.5 Communications

2580 To ensure data readout and dialog in between the machine and the TDCs or in between the webDCS
 2581 and the DAQ, different communication solutions were used. First of all, it is important to have a

2582

2583 module to allow the communication in between the TDCs and the computer from which the DAQ
 2584 operates. When this communication is effective, shifters using the webDCS to control data taking
 2585 can thus send instructions to the DAQ.

2586

2587 A.5.1 V1718 USB Bridge

2588 In the previous section, the data transfer has been discussed. The importance of the `v1718` object
 2589 (Source Code A.6), used as private member of `DataReader`, was not explicated. VME master
 2590 modules are used for communication purposes as they host the USB port that connects the pow-
 2591 ered crate buffer to the computer where the DAQ is installed. From the source code point of view,
 2592 this object is used to control the communication status, by reading the returned error codes with
 2593 `v1718::CheckStatus()`, or to check for IRQs coming from the TDCs through `v1718::CheckIRQ()`.
 2594 Finally, to ensure that triggers are blocked at the hardware level, a NIM pulse is sent out of one of the
 2595 5 programmable outputs (`v1718::SendBUSY()`) to the VETO of the coincidence module where the
 2596 trigger signals originate from. As long as this signal is ON, no trigger can reach the TDCs anymore.
 2597

```
2598
2599 class v1718{
3000     private:
3001         int Handle;
3002         Data32 Data;           // Data
3003         CVIRQLevels Level;    // Interrupt level
3004         CVAddressModifier AM;   // Addressing Mode
3005         CVDataWidth dataSize;  // Data Format
3006         Data32 BaseAddress;    // Base Address
3007
3008     public:
3009         v1718(IniFile *inifile);
3010         ~v1718();
3011         long GetHandle(void) const;
3012         int GetData(Data16 data);
3013         Data16 GetData(void);
3014         int SetLevel(CVIRQLevels level);
3015         CVIRQLevels GetLevel(void);
3016         int SetAM(CVAddressModifier am);
3017         CVAddressModifier GetAM(void);
3018         int SetDatasize(CVDataWidth datasize);
3019         CVDataWidth GetDataSize(void);
3020         int SetBaseAddress(Data16 baseaddress);
3021         Data16 GetBaseAddress(void);
3022         void CheckStatus(CVErrorCodes status) const;
3023         bool CheckIRQ();
3024         void SetPulsers();
3025         void SendBUSY(BusyLevel level);
3026     };
3027 
```

2600 *Source Code A.6: Description of C++ object v1718.*

2601 A.5.2 Configuration file

2602 The DAQ software takes as input a configuration file written using INI standard [67]. This file is
 2603 partly filled with the information provided by the shifters when starting data acquisition using the
 2604 webDCS, as shown by Figure A.6. This information is written in section [`General`] and will later

2604 be stored in the ROOT file that contains the DAQ data as can be seen from Figure A.3. Indeed,
 2605 another `TTree` called `RunParameters` as well as the 2 histograms `ID`, containing the scan number,
 2606 start and stop time stamps, and `Triggers`, containing the number of triggers requested by the shifter,
 2607 are available in the data files. Moreover, `ScanID` and `HV` are then used to construct the file name
 2608 thanks to the method `DataReader::GetFileName()`.

Chamber	RE2-2-NPD-BARC-8	RE4-2-CERN-106	RE2-3-NPD-BARC-9	RE4-2-CERN-105	RE4-2-KODEL-1-4	Max triggers
HV _{eff} 1	8600	8500	8600	8500	6500	
HV _{eff} 2	8700	8600	8700	8600	6600	
HV _{eff} 3	8800	8700	8800	8700	6700	
HV _{eff} 4	8900	8800	8900	8800	6800	
HV _{eff} 5	9000	8900	9000	8900	6900	
HV _{eff} 6	9100	9000	9100	9000	7000	
HV _{eff} 7	9200	9100	9200	9100	7100

HV _{eff} 10	9500	9400	9500	9400	7400	

Figure A.6: WebDCS DAQ scan page. On this page, shifters need to choose the type of scan (Rate, Efficiency or Noise Reference scan), the gamma source configuration at the moment of data taking, the beam configuration, and the trigger mode. These information will be stored in the DAQ ROOT output. Are also given the minimal measurement time and waiting time after ramping up of the detectors is over before starting the data acquisition. Then, the list of HV points to scan and the number of triggers for each run of the scan are given in the table underneath.

2609 The rest of the information is written beforehand in the configuration file template, as explicated
 2610 in Source Code A.7, and contains the hardware addresses to the different VME modules in the
 2611 setup as well as settings for the TDCs. As the TDC settings available in the configuration file are not
 2612 supposed to be modified, an improvement would be to remove them from the configuration file and
 2613 to hardcode them inside of the DAQ code itself or to place them into a different INI file that would
 2614 host only the TDC settings to lower the probability for a bad manipulation of the configuration file
 2615 that can be modified from one of webDCS' menus.

2617

Source Code A.7: INI configuration file template for 4 TDCs. In section [General], the number of TDCs is explicitated and information about the ongoing run is given. Then, there are sections for each and every VME modules. There buffer addresses are given and for the TDCs, the list of channels to enable is given. Finally, in section [TDCSettings], a part of the TDC settings are given.

2619 In order to retrieve the information of the configuration file, the object `IniFile` has been developed
 2620 to provide an INI parser, presented in Source Code A.8. It contains private methods returning a
 2621 boolean to check the type of line written in the file, whether a comment, a group header or a key line
 2622 (`IniFile::CheckIfComment()`, `IniFile::CheckIfGroup()` and `IniFile::CheckIfToken()`). The
 2623 key may sometimes be referred to as *token* in the source code. Moreover, the private element
 2624 `FileData` is a map of `const string` to `string` that allows to store the data contained inside the
 2625 configuration file via the public method `IniFile::GetFileData()` following the formatting (see
 2626 method `IniFile::Read()`):

```
2627
 2628     string group, token, value;
 2629     // Get the field values for the 3 strings.
 2630     // Then concatenate group and token together as a single string
 2631     // with a dot separation.
 2632     token = group + "." + token;
 2633     FileData[token] = value;
```

2629 More methods have been written to translate the different keys into the right variable format
 2630 when used by the DAQ. For example, to get a `float` value out of the configuration file data, knowing
 2631 the group and the key needed, the method `IniFile::floatType()` can be used. It takes 3 arguments
 2632 being the group name and key name (both `string`), and a default `float` value used as exception in
 2633 the case the expected combination of group and key cannot be found in the configuration file. This
 2634 default value is then used and the DAQ continues on working after sending an alert in the log file for
 2635 further debugging.

```

2636 typedef map< const string, string > IniFileData;
2637
class IniFile{
    private:
        bool          CheckIfComment (string line);
        bool          CheckIfGroup(string line, string& group);
        bool          CheckIfToken(string line, string& key, string& value);
        string         FileName;
        IniFileData   FileData;
        int           Error;

    public:
        IniFile();
        IniFile(string filename);
        virtual      ~IniFile();

        // Basic file operations
        void          SetFileName(string filename);
        int           Read();
        int           Write();
        IniFileData GetFileData();

        // Data readout methods
        Data32         addressType (string groupname, string keyname, Data32
→     defaultvalue);
        long          intType     (string groupname, string keyname, long
→     defaultvalue);
        long long    longType    (string groupname, string keyname, long long
→     defaultvalue );
        string         stringType  (string groupname, string keyname, string
→     defaultvalue );
        float         floatType   (string groupname, string keyname, float
→     defaultvalue );

        // Error methods
        string         GetErrorMsg();
    };

```

2638 *Source Code A.8: Description of C++ object `IniFile` used as a parser for INI file format.*

2639 A.5.3 WebDCS/DAQ intercommunication

2640 When shifters send instructions to the DAQ via the configuration file, it is the webDCS itself that
 2641 gives the start command to the DAQ and then the 2 softwares use inter-process communication
 2642 through file to synchronise themselves. This communication file is represented by the variable **const**
 2643 **string** __runstatuspath.

2644 On one side, the webDCS sends commands or status that are readout by the DAQ:

- 2645 ● INIT, status sent when launching a scan and read via function `CtrlRunStatus(...)`,
- 2646 ● START, command to start data taking and read via function `CheckSTART()`,
- 2647 ● STOP, command to stop data taking at the end of the scan and read via function `CheckSTOP()`,
 2648 and
- 2649 ● KILL, command to kill data taking sent by user and read via function `CheckKILL()`

2650 and on the other, the DAQ sends status that are controled by the webDCS:

- 2651 ● `DAQ_RDY`, sent with `SendDAQReady()` to signify that the DAQ is ready to receive commands
2652 from the webDCS,
- 2653 ● `RUNNING`, sent with `SendDAQRunning()` to signify that the DAQ is taking data,
- 2654 ● `DAQ_ERR`, sent with `SendDAQError()` to signify that the DAQ didn't receive the expected com-
2655 mand from the webDCS or that the launch command didn't have the right number of argu-
2656 ments,
- 2657 ● `RD_ERR`, sent when the DAQ wasn't able to read the communication file, and
- 2658 ● `WR_ERR`, sent when the DAQ wasn't able to write into the communication file.

2659 **A.5.4 Example of inter-process communication cycle**

2660 Under normal conditions, the webDCS and the DAQ processes exchange commands and status via
2661 the file hosted at the address `__runstatuspath`, as explained in subsection A.5.3. An example of
2662 cycle is given in Table A.1. In this example, the steps 3 to 5 are repeated as long as the webDCS tells
2663 the DAQ to take data. A data taking cycle is the equivalent as what is called a *Scan* in GIFT++ jargon,
2664 referring to a set a runs with several HV steps. Each repetition of steps 3 to 5 is then equivalent to a
2665 single *Run*.

2666 At any moment during the data taking, for any reason, the shifter can decide that the data taking
2667 needs to be stopped before it reached the end of the scheduled cycle. Thus at any moment on the
2668 cycle, the content of the inter-process communication file will be changed to `KILL` and the DAQ will
2669 shut down right away. The DAQ checks for `KILL` signals every 5s after the TDCs configuration is
2670 over. So far, the function `CheckKILL()` has been used only inside of the data taking loop of method
2671 `DataReader::Run()` and thus, if the shifter decides to KILL the data taking during the TDC con-
2672 figuration phase or the HV ramping in between 2 HV steps, the DAQ will not be stopped smoothly
2673 and a *force kill* command will be sent to stop the DAQ process that is still awake on the computer.
2674 Improvements can be brought on this part of the software to make sure that the DAQ can safely
2675 shutdown at any moment.

2678 **A.6 Software export**

2679 In section A.2 was discussed the fact that the DAQ as written in its last version is not a standalone
2680 software. It is possible to make it a standalone program that could be adapted to any VME setup
2681 using V1190A and V1718 modules by creating a GUI for the software or by printing the log mes-
2682 sages that are normally printed in the webDCS through the log file, directly into the terminal. This
2683 method was used by the DAQ up to version 3.0 moment where the webDCS was completed. Also, it
2684 is possible to check branches of DAQ v2.X to have example of communication through a terminal.

2685
2686 DAQ v2.X is nonetheless limited in it's possibilities and requires a lot of offline manual interven-
2687 tions from the users. Indeed, there is no communication of the software with the detectors' power
2688 supply system that would allow for a user a predefine a list of voltages to operate the detectors at

step	actions of webDCS	status of DAQ	<code>__runstatuspath</code>
1	launch DAQ ramp voltages ramping over wait for currents stabilization	readout of IniFile configuration of TDCs	INIT
2		configuration done send DAQ ready wait for START signal	DAQ_RDY
3	waiting time over send START		START
4	wait for run to end monitor DAQ run status	data taking ongoing check for KILL signal	RUNNING
5		run over send DAQ_RDY wait for next DCS signal	DAQ_RDY
6	ramp voltages ramping over wait for currents stabilization		DAQ_RDY
3	waiting time over send START		START
4	wait for run to end monitor DAQ run status	update IniFile information data taking ongoing check for KILL signal	RUNNING
5		run over send DAQ_RDY wait for next DCS signal	DAQ_RDY
7	send command STOP	DAQ shuts down	STOP

Table A.1: Inter-process communication cycles in between the webDCS and the DAQ through file string signals.

2689 and loop over to take data without any further manual intervention. In v2.X, the data is taken for a
2690 single detector setting and at the end of each run, the softwares asks the user if he intends on taking
2691 more runs. If so, the software invites the user to set the operating voltages accordingly to what is
2692 necessary and to manual update the configuration file in consequence. This working mode can be a
2693 very first approach before an evolution and has been successfully used by colleagues from different
2694 collaborations.

2695
2696 For a more robust operation, it is recommended to develop a GUI or a web application to inter-
2697 face the DAQ. Moreover, to limit the amount of manual interventions, and thus the probability to
2698 make mistakes, it is also recommended to add an extra feature into the DAQ by installing the HV
2699 Wrapper library provided by CAEN of which an example of use in a similar DAQ software devel-
2700 opped by a master student of UGent, and called TinyDAQ, is provided on UGent's github. Then, this
2701 HV Wrapper will help you communicating with and give instructions to a CAEN HV powered crate
2702 and can be added into the DAQ at the same level where the communication with the user was made
2703 in DAQ v2.X. In case you are using another kind of power system for your detectors, it is stringly
2704 adviced to use HV modules or crates that can be remotely controled via a using C++ libraries.

2707

Details on the offline analysis package

2708 The data collected in GIF++ thanks to the DAQ described in Appendix A is difficult to interpret by
2709 a human user that doesn't have a clear idea of the raw data architecture of the ROOT data files. In
2710 order to render the data human readable, a C++ offline analysis tool was designed to provide users
2711 with detector by detector histograms that give a clear overview of the parameters monitored during
2712 the data acquisition [68]. In this appendix, details about this software in the context of GIF++, as of
2713 how the software was written and how it functions will be given.

2714 B.1 GIF++ Offline Analysis file tree

2715 GIF++ Offline Analysis source code is fully available on github at https://github.com/aafagot/GIF_OfflineAnalysis. The software requires ROOT as non-optionnal dependency
2716 as it takes ROOT files in input and write an output ROOT file containing histograms. To compile the
2717 GIF++ Offline Analysis project is compiled with cmake. To compile, first a build/ directory must
2718 be created to compile from there:

```
2720 mkdir build
2721 cd build
2722 cmake ..
2723 make
2724 make install
```

2722 To clean the directory and create a new build directory, the bash script cleandir.sh can be used:

```
2723
2724 ./cleandir.sh
```

2725 The source code tree is provided below along with comments to give an overview of the files' con-
2726 tent. The different objects created for this project (`Infrastructure`, `Trolley`, `RPC`, `Mapping`, `RPCHit`,
2727 `RPCCluster` and `Inifile`) will be described in details in the following sections.

2729

B.2 Usage of the Offline Analysis

2730

In order to use the Offline Analysis tool, it is necessary to know the Scan number and the HV Step of the run that needs to be analysed. This information needs to be written in the following format:

2732

2733

```
Scan00XXXX_HVY
```

2734

where XXXX is the scan ID and Y is the high voltage step (in case of a high voltage scan, data will be taken for several HV steps). This format corresponds to the base name of data files in the database

2735

2736 of the GIF++ webDCS. Usually, the offline analysis tool is automatically called by the webDCS at
 2737 the end of data taking or by a user from the webDCS panel if an update of the tool was brought.
 2738 Nonetheless, an expert can locally launch the analysis for tests on the GIF++ computer, or a user can
 2739 get the code on its local machine from github and download data from the webDCS for its own anal-
 2740 ysis. To launch the code, the following command can be used from the `GIF_OfflineAnalysis` folder:

2741

```
2742 bin/offlineanalysis /path/to/Scan00XXXX_HVY
```

2743 where, `/path/to/Scan00XXXX_HVY` refers to the local data files. Then, the offline tool will by itself
 2744 take care of finding all available ROOT data files present in the folder, as listed below:

2745

- `Scan00XXXX_HVY_DAQ.root` containing the TDC data as described in Appendix ?? (events, hit
 2746 and timestamp lists), and
- `Scan00XXXX_HVY_CAEN.root` containing the CAEN mainframe data recorded by the monitor-
 2748 ing tool webDCS during data taking (HVs and currents of every HV channels). This file is
 2749 created independently of the DAQ.

2750

B.2.1 Output of the offline tool

2751

B.2.1.1 ROOT file

2752

The analysis gives in output ROOT datafiles that are saved into the data folder and called using the
 2753 naming convention `Scan00XXXX_HVY_Offline.root`. Inside those, a list of `TH1` histograms can be
 2754 found. Its size will vary as a function of the number of detectors in the setup as each set of histograms
 2755 is produced detector by detector. For each partition of each chamber, can be found:

2756

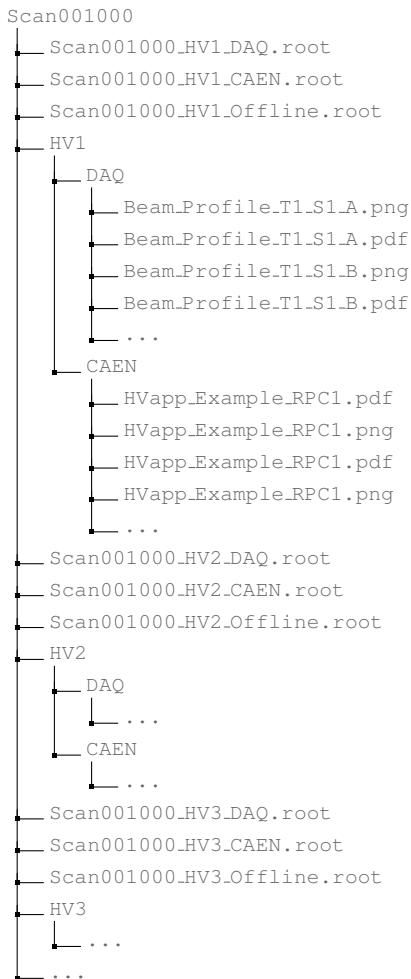

- `Time_Profile_Tt_Sc_p` shows the time profile of all recorded events (number of events per
 2757 time bin),
- `Hit_Profile_Tt_Sc_p` shows the hit profile of all recorded events (number of events per chan-
 2759 nel),
- `Hit_Multiplicity_Tt_Sc_p` shows the hit multiplicity (number of hits per event) of all recorded
 2761 events (number of occurrences per multiplicity bin),
- `Strip_Mean_Noise_Tt_Sc_p` shows noise/gamma rate per unit area for each strip in a se-
 2763 lected time range. After filters are applied on `Time_Profile_Tt_Sc_p`, the filtered version
 2764 of `Hit_Profile_Tt_Sc_p` is normalised to the total integrated time and active detection area
 2765 of a single channel,
- `Strip_Activity_Tt_Sc_p` shows noise/gamma activity for each strip (normalised version of
 2767 previous histogram - strip activity = strip rate / average partition rate),
- `Strip_Homogeneity_Tt_Sc_p` shows the *homogeneity* of a given partition ($\text{homogeneity} = \exp(-\text{strip rates standard deviation(strip rates in partition/average partition rate)})$),
- `mask_Strip_Mean_Noise_Tt_Sc_p` shows noise/gamma rate per unit area for each masked
 2771 strip in a selected time range. Offline, the user can control the noise/gamma rate and decide to
 2772 mask the strips that are judged to be noisy or dead. This is done via the *Masking Tool* provided
 2773 by the webDCS,

- 2774 ● `mask_Strip_Activity_Tt_Sc_p` shows noise/gamma activity per unit area for each masked
2775 strip with respect to the average rate of active strips,
- 2776 ● `NoiseCSize_H_Tt_Sc_p` shows noise/gamma cluster size, a cluster being constructed out of
2777 adjacent strips giving a signal at the *same time* (hits within a time window of 25 ns),
- 2778 ● `NoiseCMult_H_Tt_Sc_p` shows noise/gamma cluster multiplicity (number of reconstructed
2779 clusters per event),
- 2780 ● `Chip_Mean_Noise_Tt_Sc_p` shows the same information than `Strip_Mean_Noise_Tt_Scp` us-
2781 ing a different binning (1 chip corresponds to 8 strips),
- 2782 ● `Chip_Activity_Tt_Sc_p` shows the same information than `Strip_Activity_Tt_Scp` using
2783 chip binning,
- 2784 ● `Chip_Homogeneity_Tt_Sc_p` shows the homogeneity of a given partition using chip binning,
- 2785 ● `Beam_Profile_Tt_Sc_p` shows the estimated beam profile when taking efficiency scan. This
2786 is obtained by filtering `Time_Profile_Tt_Sc_p` to only consider the muon peak where the
2787 noise/gamma background has been subtracted. The resulting hit profile corresponds to the
2788 beam profile on the detector channels,
- 2789 ● `L0_Efficiency_Tt_Sc_p` shows the level 0 efficiency that was estimated **without** muon track-
2790 ing,
- 2791 ● `MuonCSize_H_Tt_Sc_p` shows the level 0 muon cluster size that was estimated **without** muon
2792 tracking, and
- 2793 ● `MuonCMult_H_Tt_Sc_p` shows the level 0 muon cluster multiplicity that was estimated **without**
2794 muon tracking.

2795 In the histogram labels, t stands for the trolley number (1 or 3), c for the chamber slot label in
2796 trolley t and p for the partition label (A, B, C or D depending on the chamber layout) as explained
2797 in Chapter 5.4.

2798 In the context of GIF++, an extra script called by the webDCS is called to extract the histograms
2799 from the ROOT files. The histograms are then stored in PNG and PDF formats into the correspond-
2800 ing folder (a single folder per HV step, so per ROOT file). the goal is to then display the histograms
2801 on the Data Quality Monitoring (DQM) page of the webDCS in order for the users to control the
2802 quality of the data taking at the end of data taking. An example of histogram organisation is given
2803 below:

2804

2806 ***Here can put some screens from the webDCS to show the DQM and the plots available to users.***
 2807

2808 **B.2.1.2 CSV files**

2809 Moreover, up to 3 CSV files can be created depending on which ones of the 3 input files were in the
 2810 data folder:

- 2811 ● `Offline-Corrupted.csv` , is used to keep track of the amount of data that was corrupted and
 2812 removed from old data format files that don't contain any data quality flag.
- 2813 ● `Offline-Current.csv` , contains the summary of the currents and voltages applied on each
 2814 RPC HV channel.
- 2815 ● `Offline-L0-EffC1.csv` , is used to write the efficiencies, cluster size and cluster multiplicity
 2816 of efficiency runs. Note that `L0` refers here to *Level 0* and means that the results of efficiency and
 2817 clusterization are a first approximation calculated without performing any muon tracking in

2818 between the different detectors. This offline tool provides the user with a preliminar calculation
 2819 of the efficiency and of the muon event parameters. Another analysis software especially
 2820 dedicated to muon tracking is called on selected data to retrieve the results of efficiency and
 2821 muon clusterization using a tracking algorithm to discriminate noise or gamma from muons
 2822 as muons are the only particles that pass through the full setup, leaving hits than can be used
 2823 to reconstruct their tracks.

- 2824
 - `Offline-Rate.csv`, is used to write the noise or gamma rates measured in the detector readout
 2825 partitions.

2826 Note that these 4 CSV files are created along with their *headers* (`Offline-[...]-Header.csv`
 2827 containing the names of each data columns) and are automatically merged together when the offline
 2828 analysis tool is called from the webDCS, contrary to the case where the tool is runned locally from
 2829 the terminal as the merging bash script is then not called. Thus, the resulting files, used to make
 2830 official plots, are:

- 2831
 - `Corrupted.csv`,
 - `Current.csv`,
 - `L0-EffCl.csv`.
- 2834
 - `Rate.csv`.

2835 **B.3 Analysis inputs and information handling**

2836 The usage of the Offline Analysis tool as well as its output have been presented in the previous section.
 2837 It is now important to dig further and start looking at the source code and the inputs necessary
 2838 for the tool to work. Indeed, other than the raw ROOT data files that are analysed, more information
 2839 needs to be imported inside of the program to perform the analysis such as the description of the
 2840 setup inside of GIFT++ at the time of data taking (number of trolleys, of RPCs, dimensions of the
 2841 detectors, etc...) or the mapping that links the TDC channels to the coresponding RPC channels in
 2842 order to translate the TDC information into human readable data. 2 files are used to transmit all this
 2843 information:

- 2844
- 2845
 - `Dimensions.ini`, that provides the necessary setup and RPC information, and
 - `ChannelsMapping.csv`, that gives the link between the TDC and RPC channels as well as the
 2846 *mask* for each channel (masked or not?).

2848 **B.3.1 Dimensions file and InFile parser**

2849 This input file, present in every data folder, allows the analysis tool to know of the number of active
 2850 trolleys, the number of active RPCs in those trolleys, and the details about each RPCs such as
 2851 the number of RPC gaps, the number of pseudo-rapidity partitions (for CMS-like prototypes), the
 2852 number of strips per partion or the dimensions. To do so, there are 3 types of groups in the INI file
 2853 architecture. A first general group, appearing only once at the head of the document, gives information
 2854 about the number of active trolleys as well as their IDs, as presented in Source Code B.1. For

2855 each active trolley, a group similar to Source Code B.2 can be found containing information about
 2856 the number of active detectors in the trolley and their IDs. Each trolley group as a `Tt` name format,
 2857 where `t` is the trolley ID. Finally, for each detector stored in slots of an active trolley, there is a group
 2858 providing information about their names and dimensions, as shown in Source Code B.3. Each slot
 2859 group as a `TtSs` name format, where `s` is the slot ID of trolley `t` where the active RPC is hosted.

```
2860
2861 [General]
2862 nTrolleys=2
2863 TrolleysID=13
```

2862 *Source Code B.1: Example of `[General]` group as might be found in `Dimensions.ini`. In Gif++, only 2 trolleys are available to hold RPCs and place them inside of the bunker for irradiation. The IDs of the trolleys are written in a single string as "13" and then read character by character by the program.*

```
2863
2864 [T1]
2865 nSlots=4
2866 SlotsID=1234
```

2864 *Source Code B.2: Example of trolley group as might be found in `Dimensions.ini`. In this example, the file tells that there are 4 detectors placed in the holding slots of the trolley `T1` and that their IDs, written as a single string variable, are 1, 2, 3 and 4.*

```
2865
2866 [T1S1]
2867 Name=RE2-2-NPD-BARC-8
2868 Partitions=3
2869 Gaps=3
2870 Gap1=BOT
2871 Gap2=TN
2872 Gap3=TW
2873 AreaGap1=11694.25
2874 AreaGap2=6432
2875 AreaGap3=4582.82
2876 Strips=32
2877 ActiveArea-A=157.8
2878 ActiveArea-B=121.69
2879 ActiveArea-C=93.03
```

2870 *Source Code B.3: Example of slot group as might be found in `Dimensions.ini`. In this example, the file provides information about a detector named `RE2-2-NPD-BARC-8`, having 3 pseudo-rapidity readout partitions and stored in slot `S1` of trolley `T1`. This is a CMS RE2-2 type of detector. This information will then be used for example to compute the rate per unit area calculation.*

2871 This information is readout and stored in a C++ object called `IniFile`, that parses the information
 2872 in the INI input file and stores it into a local buffer for later use. This INI parser is the exact same
 2873 one that was previously developed for the Gif++ DAQ and described in Appendix A.5.2.

2870 B.3.2 TDC to RPC link file and Mapping

2871 The same way the INI dimension file information is stored using `map`, the channel mapping and mask
 2872 information is stored and accessed through `map`. First of all, the mapping CSV file is organised into
 2873 3 columns separated by tabulations (and not by commas, as expected for CSV files as it is easier using
 2874 streams to read tab or space separated data using C++):

2875

2876 RPC_channel TDC_channel mask

2877 using as formatting for each field:

2878
2879 TSCCC TCCC M

2880 TSCCC is a 5-digit integer where τ is the trolley ID, s the slot ID in which the RPC is held insite
2881 the trolley τ and ccc is the RPC channel number, or *strip* number, that can take values up to
2882 3-digits depending on the detector,

2883 TCCC is a 4 digit integer where τ is the TDC ID, ccc is the TDC channel number that can take values
2884 in between 0 and 127, and

2885 M is a 1-digit integer indicating if the channel should be considered ($M = 1$) or discarded ($M = 0$)
2886 during analysis.

2887 This mapping and masking information is readout and stored thanks to the object `Mapping`, pre-
2888 sented in Source Code B.4. Similarly to `IniFile` objects, this class has private methods. The first
2889 one, `Mapping::CheckIfNewLine()` is used to find the newline character '`\n`' or return character
2890 '`\r`' (depending on which kind of operating system interacted with the file). This is used for the
2891 simple reason that the masking information has been introduced only during the year 2017 but the
2892 channel mapping files exist since 2015 and the very beginning of data taking at GIF++. This means
2893 that in the older data folders, before the upgrade, the channel mapping file only had 2 columns, the
2894 RPC channel and the TDC channel. For compatibility reasons, this method helps controling the
2895 character following the readout of the 2 first fields of a line. In case any end of line character is
2896 found, no mask information is present in the file and the default $M = 1$ is used. On the contrary, if
2897 the next character was a tabulation or a space, the mask information is present.

2898 Once the 3 fields have been readout, the second private method `Mapping::CheckIfTDCCh()` is
2899 used to control that the TDC channel is an existing TDC channel. Finally, the information is stored
2900 into 3 different maps (`Link`, `ReverseLink` and `Mask`) thanks to the public method `Mapping::Read()`.
2901 `Link` allows to get the RPC channel by knowing the TDC channel while `ReverseLink` does the op-
2902 posite by returning the TDC channel by knowing the RPC channel. Finally, `Mask` returns the mask
2903 associated to a given RPC channel.

```

2904 typedef map<Uint,Uint> MappingData;
2905
2906 class Mapping {
2907     private:
2908         bool          CheckIfNewLine(char next);
2909         bool          CheckIfTDCCh(Uint channel);
2910         string        FileName;
2911         MappingData  Link;
2912         MappingData  ReverseLink;
2913         MappingData  Mask;
2914         int           Error;
2915
2916     public:
2917         Mapping();
2918         Mapping(string baseName);
2919         ~Mapping();
2920
2921         void SetFileName(const string filename);
2922         int  Read();
2923         Uint GetLink(Uint tdcchannel);
2924         Uint GetReverse(Uint rpcchannel);
2925         Uint GetMask(Uint rpcchannel);
2926     };

```

2906 *Source Code B.4: Description of C++ object Mapping used as a parser for the channel mapping and mask file.*

2907 B.4 Description of GIF++ setup within the Offline Analysis tool

2908 In the previous section, the tool input files have been discussed. The dimension file information is
 2909 stored in a map hosted by the `IniFile` object. But this information is then used to create a series of
 2910 new objects that helps defining the GIF++ infrastructure directly into the Offline Analysis. Indeed,
 2911 from the `RPC`, to the more general `Infrastructure`, every element of the GIF++ infrastrucutre is
 2912 recreated for each data analysis based on the information provided in input. All this information
 2913 about the infrastructure will be used to assign each hit signal to a specific strip channel of a specific
 2914 detector, and having a specific active area. This way, rate per unit area calculation is possible.
 2915

2916 B.4.1 RPC objects

2917 `RPC` objects have been developped to represent physical active detectors in GIF++ at the moment
 2918 of data taking. Thus, there are as many `RPC` objects created during the analysis than there were
 2919 active `RPCs` tested during a run. Each `RPC` hosts the information present in the corresponding INI
 2920 slot group, as shown in B.3, and organises it using a similar architecture. This can be seen from
 2921 *Source Code B.5*.

2922 To make the object more compact, the lists of gap labels, of gap active areas and strip active
 2923 areas are stored into `vector` dynamical containers. `RPC` objects are always contructed thanks to the
 2924 dimension file information stored into the `IniFILE` and their ID, using the format `TtSs`. Using the
 2925 `RPC` ID, the constructor calls the methods of `IniFILE` to initialise the `RPC`. The other constructors
 2926 are not used but exist in case of need. Finally, some getters have been written to access the different
 2927 private parameters storing the detector information.

```

2928
class RPC{
    private:
        string      name;           //RPC name as in webDCS database
        Uint        nGaps;          //Number of gaps in the RPC
        Uint        nPartitions;    //Number of partitions in the RPC
        Uint        nStrips;         //Number of strips per partition
        vector<string> gaps;       //List of gap labels (BOT, TOP, etc...)
        vector<float>  gapGeo;        //List of gap active areas
        vector<float>  stripGeo;      //List of strip active areas

    public:
        RPC();
        RPC(string ID, IniFile* geofile);
        RPC(const RPC& other);
        ~RPC();
        RPC& operator=(const RPC& other);

        string GetName();
        Uint GetNGaps();
        Uint GetNPartitions();
        Uint GetNStrips();
        string GetGap(Uint g);
        float GetGapGeo(Uint g);
        float GetStripGeo(Uint p);
};

2929

```

2930 *Source Code B.5: Description of C++ objects RPC that describe each active detectors used during data taking.*

2931 B.4.2 Trolley objects

2932 Trolley objects have been developped to represent physical active trolleys in GIFT++ at the moment
 2933 of data taking. Thus, there are as many trolley objects created during the analysis than there were
 2934 active trolleys hosting tested RPCs during a run. Each Trolley hosts the information present in the
 2935 corresponding INI trolley group, as shown in B.2, and organises it using a similar architecture. In
 2936 addition to the information hosted in the INI file, these object have a dynamical container of RPC
 2937 objects, representing the active detectors the active trolley was hosting at the time of data taking.
 2938 This can been seen from Source Code B.6.

2939 Trolley objects are always contructed thanks to the dimension file information stored into the
 2940 IniFILE and their ID, using the format Tt. Using the Trolley ID, the constructor calls the methods
 2941 of IniFILE to initialise the Trolley. Retrieving the information of the RPC IDs via SlotsID, a new
 2942 RPC is constructed and added to the container RPCs for each character in the ID string. The other
 2943 constructors are not used but exist in case of need. Finally, some getters have been written to access
 2944 the different private parameters storing the trolley and detectors information.

```

2945 class Trolley{
2946     private:
        Uint          nSlots; //Number of active RPCs in the considered trolley
        string        SlotsID; //Active RPC IDs written into a string
        vector<RPC*> RPCs;   //List of active RPCs
2947
    public:
        //Constructors, destructor and operator =
        Trolley();
        Trolley(string ID, IniFile* geofile);
        Trolley(const Trolley& other);
        ~Trolley();
        Trolley& operator=(const Trolley& other);
2948
        //Get GIFTrolley members
        Uint  GetNSlots();
        string GetSlotsID();
        Uint   GetSlotID(Uint s);
2949
        //Manage RPC list
        RPC*  GetRPC(Uint r);
        void  DeleteRPC(Uint r);
2950
        //Methods to get members of RPC objects stored in RPCs
        string GetName(Uint r);
        Uint   GetNGaps(Uint r);
        Uint   GetNPartitions(Uint r);
        Uint   GetNStrips(Uint r);
        string GetGap(Uint r, Uint g);
        float  GetGapGeo(Uint r, Uint g);
        float  GetStripGeo(Uint r, Uint p);
    };

```

Source Code B.6: Description of C++ objects Trolley that describe each active trolley used during data taking.

2948 B.4.3 Infrastructure object

2949 The `Infrastructure` object has been developped to represent the GIFT++ bunker area dedicated to
 2950 CMS RPC experiments. With this very specific object, all the information about the CMS RPC
 2951 setup within GIFT++ at the moment of data taking is stored. It hosts the information present in the
 2952 corresponding INI general group, as shown in B.1, and organises it using a similar architecture. In
 2953 addition to the information hosted in the INI file, this object have a dynamical container of `Trolley`
 2954 objects, representing the active tolleys in GIFT++ area. This can be seen from Source Code B.7.

2955 The `Infrastructure` object is always contructed thanks to the dimension file information stored
 2956 into the `IniFILE`. Retrieving the information of the trolley IDs via `TrolleysID`, a new `Trolley` is
 2957 constructed and added to the container `Trolleys` for each character in the ID `string`. By extension,
 2958 it is easy to understand that the process described in Section B.4.2 for the construction of RPCs
 2959 takes place when a trolley is constructed. The other constructors are not used but exist in case of
 2960 need. Finally, some getters have been written to access the different private parameters storing the
 2961 infrastructure, tolleys and detectors information.

```

2962
class Infrastructure {
    private:
        Uint             nTrolleys;   //Number of active Trolleys in the run
        string          TrolleysID;  //Active trolley IDs written into a string
        vector<Trolley*> Trolleys;  //List of active Trolleys (struct)

    public:
        //Constructors and destructor
        Infrastructure();
        Infrastructure(IniFile* geofile);
        Infrastructure(const Infrastructure& other);
        ~Infrastructure();
        Infrastructure& operator=(const Infrastructure& other);

        //Get Infrastructure members
        Uint  GetNTrolleys();
        string GetTrolleysID();
        Uint   GetTrolleyID(Uint t);

2963
        //Manage Trolleys
        Trolley* GetTrolley(Uint t);
        void     DeleteTrolley(Uint t);

        //Methods to get members of GIFTrolley objects stored in Trolleys
        Uint  GetNSlots(Uint t);
        string GetSlotsID(Uint t);
        Uint   GetSlotID(Uint t, Uint s);
        RPC*  GetRPC(Uint t, Uint r);

        //Methods to get members of RPC objects stored in RPCs
        string GetName(Uint t, Uint r);
        Uint   GetNGaps(Uint t, Uint r);
        Uint   GetNPartitions(Uint t, Uint r);
        Uint   GetNStrips(Uint t, Uint r);
        string GetGap(Uint t, Uint r, Uint g);
        float  GetGapGeo(Uint t, Uint r, Uint g);
        float  GetStripGeo(Uint t, Uint r, Uint p);
    };

```

Source Code B.7: Description of C++ object Infrastructure that contains the full information about CMS RPC experiment in GIF++.

2965 B.5 Handeling of data

2966 As discussed in Appendix A.4.2, the raw data as a `TTree` architecture where every entry is related to
 2967 a trigger signal provided by a muon or a random pulse, whether the goal of the data taking was to
 2968 measure the performance of the detector or the noise/gamma background respectively. Each of these
 2969 entries, referred also as events, contain a more or less full list of hits in the TDC channels to which
 2970 the detectors are connected. To this list of hits corresponds a list of time stamps, marking the arrival
 2971 of the hits within the TDC channel.

2972 The infrastructure of the CMS RPC experiment within `GIF++` being defined, combining the
 2973 information about the raw data with the information provided by both the mapping/mask file and the
 2974 dimension file allows to build new physical objects that will help in computing efficiency or rates.

2975 B.5.1 RPC hits

2976 The raw data stored in the ROOT file as output of the GIFT++ DAQ, is readout by the analysis tool
 2977 using the structure `RAWData` presented in Source Code B.9 that differs from the structure presented
 2978 in Appendix A.4.2 as it is not meant to hold all of the data contained in the ROOT file. In this sense,
 2979 this structure is in the case of the offline analysis tool not a dynamical object and will only be storing
 2980 a single event contained in a single entry of the `TTree`.

```
2981
  class RPCHit {
    private:
      Uint Channel;      //RPC channel according to mapping (5 digits)
      Uint Trolley;     //0, 1 or 3 (1st digit of the RPC channel)
      Uint Station;     //Slot where is held the RPC in Trolley (2nd digit)
      Uint Strip;       //Physical RPC strip where the hit occurred (last 3
→   digits)
      Uint Partition;   //Readout partition along eta segmentation
      float TimeStamp; //Time stamp of the arrival in TDC

    public:
      //Constructors, destructor & operator =
      RPCHit();
      RPCHit(Uint channel, float time, Infrastructure* Infra);
      RPCHit(const RPCHit& other);
      ~RPCHit();
      RPCHit& operator=(const RPCHit& other);

      //Get RPCHit members
      Uint GetChannel();
      Uint GetTrolley();
      Uint GetStation();
      Uint GetStrip();
      Uint GetPartition();
      float GetTime();
    };

    typedef vector<RPCHit> HitList;
    typedef struct GIFHitList { HitList rpc[NTROLLEYS][NSLOTS][NPARTITIONS]; }
→   GIFHitList;

    bool SortHitbyStrip(RPCHit h1, RPCHit h2);
    bool SortHitbyTime(RPCHit h1, RPCHit h2);
  }
```

2983 *Source Code B.8: Description of C++ object `RPCHit`.*

```
2984
  struct RAWData{
    int iEvent;        //Event i
    int TDCNHits;    //Number of hits in event i
    int QFlag;         //Quality flag list (1 flag digit per TDC)
    vector<Uint> *TDCCh; //List of channels giving hits per event
    vector<float> *TDCTS; //List of the corresponding time stamps
  };
  
```

2985 *Source Code B.9: Description of C++ structure `RAWData`.*

2986 Each member of the structure is then linked to the corresponding branch of the ROOT data tree,
 2987 as shown in the example of Source Code B.10, and using the method `GetEntry(int i)` of the ROOT
 2988 class `TTree` will update the state of the members of `RAWData`.

```

2989   TTree* dataTree = (TTree*)dataFile.Get("RAWData");
2990   RAWData data;
2991
2992   dataTree->SetBranchAddress("EventNumber", &data.iEvent);
2993   dataTree->SetBranchAddress("number_of_hits", &data.TDCNHits);
2994   dataTree->SetBranchAddress("Quality_flag", &data.QFlag);
2995   dataTree->SetBranchAddress("TDC_channel", &data.TDCCh);
2996   dataTree->SetBranchAddress("TDC_TimeStamp", &data.TDCTS);
2997

```

2991 *Source Code B.10: Example of link in between RAWData and TTree.*

2992 The data is then analysed entry by entry and to each element of the TDC channel list, a `RPCHit` is
 2993 constructed by linking each TDC channel to the corresponding RPC channel thanks to the `Mapping`
 2994 object. The information carried by the RPC channel format allows to easily retrieve the trolley and
 2995 slot from which the hit was recorded (see section B.3.2). Using these 2 values, the readout partition
 2996 can be found by knowing the strip channel and comparing it with the number of partitions and strips
 2997 per partition stored into the `Infrastructure` object.

2998 Thus `RPCHit` objects are then stored into 3D dynamical list called `GIFHitList` (Source Code B.9)
 2999 where the 3 dimensions refer to the 3 layers of the readout in `GIF++` : in the bunker there are *trolleys*
 3000 (τ) holding detectors in *slots* (s) and each detector readout is divided into 1 or more pseudo-rapidity
 3001 *partitions* (p). Using these 3 information allows to assign an address to each readout partition and
 3002 this address will point to a specific hit list.

3003

3004 **B.5.2 Clusters of hits**

3005 All the hits contained in the ROOT file have been sorted into the different hit lists through the
 3006 `GIFHitList`. At this point, it is possible to start looking for clusters. A cluster is a group of adjacent
 3007 strips getting hits within a time window of 25 ns. These strips are then assumed to be part of the same
 3008 physical avalanche signal generated by a muon passing through the chamber or by the interaction of
 3009 a gamma stopping into the electrodes of the RPCs.

3010 To keep the cluster information, `RPCCluster` objects have been defined as shown in Source
 3011 Code B.11. Using the information of each individual `RPCHit` taken out of the hit list, it stores
 3012 the cluster size (number of adjacent strips composing the cluster), the first and last hit, the center for
 3013 spatial reconstruction and finally the start and stop time stamps as well as te time spread in between
 3014 the first and last hit.

```

3015
class RPCCluster{
    private:
        Uint ClusterSize; //Size of cluster #ID
        Uint FirstStrip; //First strip of cluster #ID
        Uint LastStrip; //Last strip of cluster #ID
        float Center; //Center of cluster #ID ((first+last)/2)
        float StartStamp; //Time stamp of the earliest hit of cluster #ID
        float StopStamp; //Time stamp of the latest hit of cluster #ID
        float TimeSpread; //Time difference between earliest and latest hits
                           //of cluster #ID

    public:
        //Constructors, destructor & operator =
        RPCCluster();
        RPCCluster(HitList List, Uint cID, Uint cSize, Uint first, Uint firstID);
        RPCCluster(const RPCCluster& other);
        ~RPCCluster();
        RPCCluster& operator=(const RPCCluster& other);

        //Get Cluster members
        Uint GetID();
        Uint GetSize();
        Uint GetFirstStrip();
        Uint GetLastStrip();
        float GetCenter();
        float GetStart();
        float GetStop();
        float GetSpread();
};

typedef vector<RPCCluster> ClusterList;

//Other functions to build cluster lists out of hit lists
void BuildClusters(HitList &cluster, ClusterList &clusterList);
void Clusterization(HitList &hits, TH1 *hcSize, TH1 *hcMult);

```

Source Code B.11: Description of C++ object cluster.

To investigate the hit list of a given detector partition, the function `Clusterization()` defined in `include/Cluster.h` needs the hits in the list to be time sorted. This is achieved by calling function `sort()` of library `<algorithm>` using the comparator `SortHitbyTime(RPCHit h1, RPCHit h2)` defined in `include/RPCHit.h` that returns `true` if the time stamp of hit `h1` is lower than that of `h2`. A first isolation of strips is made only based on time information. All the hits within the 25 ns window are taken separately from the rest. Then, this sub-list of hits is sorted this time by ascending strip number, using this time the comparator `SortHitbyStrip(RPCHit h1, RPCHit h2)`. Finally, the groups of adjacent strips are used to construct `RPCCluster` objects that are then stored in a temporary list of clusters that is at the end of the process used to know how many clusters were reconstructed and to fill their sizes into an histogram that will allows to know the mean size of muon or gamma clusters.

3030 B.6 DAQ data Analysis

3031 All the ingredients to analyse GIF++ data have been defined. This section will focus on the different
3032 part of the analysis performed on the data, from determining the type of data the tool is dealing with

3033 to calculating the rate in each detector or reconstructing muon or gamma clusters.

3034 B.6.1 Determination of the run type

3035 In GIF++, both the performance of the detectors in detecting muons in an irradiated environment and
 3036 the gamma background can be independantly measured. These corresponds to different run types
 3037 and thus, to different TDC settings giving different data to look at.

3038

3039 In the case of performance measurements, the trigger for data taking is provided by the coïncidence
 3040 of several scintillators when muons from the beam passing through the area are detected. Data
 3041 is collected in a 600 ns wide window around the arrival of muons in the RPCs. The expected time
 3042 distribution of hits is shown in Figure B.1a. The muon peak is clearly visible in the center of the
 3043 distribution and is to be extracted from the gamma background that composes the flat part of the
 3044 distribution.

3045 On the other hand, gamma background or noise measurements are focussed on the non muon
 3046 related physics and the trigger needs to be independant from the muons to give a good measurement
 3047 of the gamma/noise distribution as seen by the detectors. The trigger is then provided by a pulse
 3048 generator at a frequency of 300 Hz whose pulse is not likely to be on time with a muon. In order
 3049 to increase the integrated time without increasing the acquisition time too much, the width of the
 3050 acquisition windows are increased to 10 μ s. The time distribution of the hits is expected to be flat, as
 3051 shown by Figure B.1b.

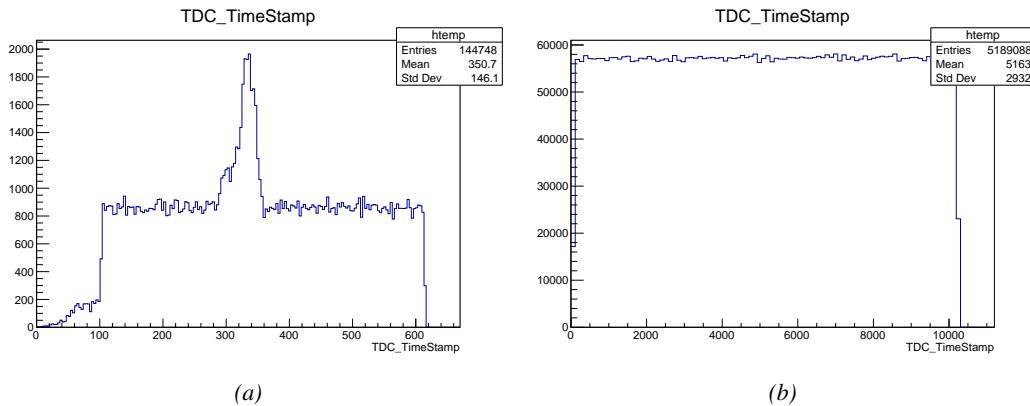

Figure B.1: Example of expected hit time distributions in the cases of efficiency (Figure B.1a) and noise/gamma rate per unit area (Figure B.1b) measurements as extracted from the raw ROOT files. The unit along the x-axis corresponds to ns. The fact that "the" muon peak is not well defined in Figure B.1a is due to the contribution of all the RPCs being tested at the same time that don't necessarily have the same signal arrival time. Each individual peak can have an offset with the ones of other detectors. The inconsistency in the first 100 ns of both time distributions is an artefact of the TDCs and are systematically rejected during the analysis.

3052 The ROOT files include a TTree called RunParameters containing, among other things, the in-
 3053 formation related to the type of run. The run type can then be accessed as described by Source
 3054 Code B.12 and the function IsEfficiencyRun() is then used to determine if the run file is an effi-
 3055 ciency run or, on the contrary, another type of run (noise or gamma measurement).

```

3056     TTree* RunParameters = (TTree*)dataFile.Get("RunParameters");
3057     TString* RunType = new TString();
3058     RunParameters->SetBranchAddress("RunType", &RunType);
3059     RunParameters->GetEntry(0);

```

3058 *Source Code B.12: Access to the run type contained in TTree* RunParameters.*

3059 Finally, the data files will have a slightly different content whether it was collected before or after
 3060 October 2017 and the upgrade of the DAQ software that brought a new information into the ROOT
 3061 output. This is discussed in Appendix A.4.3 and implies that the analysis will differ a little depending
 3062 on the data format. Indeed, as no information on the data quality is stored, in older data files, the cor-
 3063 rections for missing events has to be done at the end of the analysis. The information about the type
 3064 of data format is stored in the variable **bool** `isNewFormat` by checking the list of branches contained
 3065 in the data tree via the methods `TTree::GetListOfBranches()` and `TCollection::Contains()`.

3066 **B.6.2 Beam time window calculation for efficiency runs**

3067 Knowing the run type is important first of all to know the width of the acquisition window to be used
 3068 for the rate calculation and finally to be able to seek for muons. Indeed, the peak that appears in the
 3069 time distribution for each detectors is then fitted to extract the most probable time window in which
 3070 the tool should look for muon hits. The data outside of this time window is then used to evaluate the
 3071 noise or gamma background the detector was subjected to during the data taking. Computing the
 3072 position of the peak is done calling the function `SetBeamWindow()` defined in file `src/RPCHit.cc` that
 3073 loops a first time on the data. The data is first sorted in a 3D array of 1D histograms (`GIFH1Array`, see
 3074 include/types.h). Then the location of the highest bin is determined using `TH1::GetMaximumBin()`
 3075 and is used to define a window in which a gaussian fit will be applied to compute the peak width.
 3076 This window is a 80 ns defined by Formula B.1 around the central bin.

$$t_{center}(ns) = bin \times width_{bin}(ns) \quad (\text{B.1a})$$

$$[t_{low}; t_{high}] = [t_{center} - 40; t_{center} + 40] \quad (\text{B.1b})$$

3077 Before the fit is performed, the average number of noise/gamma hits per bin is evaluated using
 3078 the data outside of the fit window. Excluding the first 100 ns, the average number of hits per bin
 3079 due to the noise or gamma is defined by Formula B.2 after extracting the amount of hits in the time
 3080 windows $[100; t_{low}]$ and $[t_{high}; 600]$ thanks to the method `TH1::Integral()`. This average number
 3081 of hits is then subtracted to every bin of the 1D histogram, in order to *clean* it from the noise or
 3082 gamma contribution as much as possible to improve the fit quality. Bins where $\langle n_{hits} \rangle$ is greater
 3083 than the actual bin content are set to 0.

$$\Delta t_{noise}(ns) = 600 \overbrace{-t_{high} + t_{low}}^{-80ns} - 100 = 420ns \quad (\text{B.2a})$$

$$\langle n_{hits} \rangle = width_{bin}(ns) \times \frac{\sum_{t=100}^{t_{low}} + \sum_{t=t_{high}}^{600}}{\Delta t_{noise}(ns)} \quad (\text{B.2b})$$

3084 Finally, the fit parameters are extracted and saved for each detector in 3D arrays of **float**
 3085 (`muonPeak`, see include/types.h), a first one for the mean arrival time of the muons, `PeakTime`,

3086 and a second one for the width of the peak, `PeakWidth`. The width is defined as 6σ of the gaussian
 3087 fit. The same settings are applied to every partitions of the same detector. To determine which one
 3088 of the detector's partitions is directly illuminated by the beam, the peak height of each partition is
 3089 compared and the highest one is then used to define the peak settings.

3090 **B.6.3 Data loop and histogram filling**

3091 3D arrays of histogram are created to store the data and display it on the DQM of G4F++ webDCS
 3092 for the use of shifters. These histograms, presented in section B.2.1.1, are filled while looping on
 3093 the data. Before starting the analysis loop, it is necessary to control the entry quality for the new
 3094 file formats featuring `QFlag`. If the `QFlag` value for this entry shows that 1 TDC or more have a
 3095 `CORRUPTED` flag, then this event is discarded. The loss of statistics is low enough to be neglected.
 3096 `QFlag` is controlled using the function `IsCorruptedEvent()` defined in `src/utils.cc`. As explained
 3097 in Appendix A.4.3, each digit of this integer represent a TDC flag that can be 1 or 2. Each 2 is
 3098 the sign of a `CORRUPTED` state. Then, the data is accessed entry by entry in the ROOT `TTree` using
 3099 `RAWData` and each hit in the hit list is assigned to a detector channel and saved in the corresponding
 3100 histograms. In the first part of the analysis, in which the loop over the ROOT file's content is
 3101 performed, the different steps are:

3102 **1- RPC channel assignment and control:** a check is done on the RPC channel extracted thanks
 3103 to the mapping via the method `Mapping::GetLink()`. If the channel is not initialised and is 0, or if
 3104 the TDC channel was greater than 5127, the hit is discarded. This means there was a problem in the
 3105 mapping. Often a mapping problem leads to the crash of the offline tool.

3106 **2- Creation of a `RPCHit` object:** to easily get the trolley, slot and partition in which the hit has
 3107 been assigned, this object is particularly helpful.

3108 **3- General histograms are filled:** the hit is filled into the time distribution and the general hit
 3109 distribution histograms, and if the arrival time is within the first 100 ns, it is discarded and nothing
 3110 else happens and the loop proceeds with the next hit in the list.

3111 **4- Multiplicity counter:** the hit multiplicity counter of the corresponding detectors incremented.

3112 **5-a- Efficiency runs - Is the hit within the peak window? :** if the peak is contained in the peak
 3113 window previously defined in section B.6.2, the hit is filled into the beam hit profile histogram of
 3114 the corresponding chamber, added into the list of muon hits and increments the counter of *in time*
 3115 hits. The term *in time* here refers to the hits that are likely to be muons by arriving in the expected
 3116 time window. If the hit is outside of the peak window, it is filled into the noise profile histogram
 3117 of the corresponding detector, added into the list of noise/gamma hits and increments the counter of
 3118 noise/gamma hits.

3119 **5-b- Noise/gamma rate runs - Noise histograms are filled:** the hit is filled into the noise profile
 3120 histogram of the corresponding detector, added into the list of noise/gamma hits and increments the
 3121 counter of noise/gamma hits.

3122

3123 After the loop on the hit list of the entry is over, the next step is to clusterize the 3D lists filled
 3124 in the previous steps. A 3D loop is then started over the active trolley, slot and RPC partitions to
 3125 access these objects. Each `NoiseHitList` and `MuonHitList`, in case of efficiency run, are clusterized
 3126 as described in section B.5.2. There corresponding cluster size and multiplicity histograms are filled
 3127 at the end of the clustering process. Then, the efficiency histogram is filled in case of efficiency run.
 3128 The selection is simply made by checking whether the RPC detected signals in the peak window
 3129 during this event. Nevertheless, it is useful to highlight that at this level, it is not possible yet to
 3130 discriminate in between a muon hit and noise or gamma hit. Thus, `MuonCSize_H`, `MuonCMult_H`
 3131 and `Efficiency0_H` are subjected to noise and gamma contamination. This contamination will be
 3132 estimated and corrected at the moment the results will be written into output CSV files. Finally, the
 3133 loop ends on the filling of the general hit multiplicity histogram.

3134 **B.6.4 Results calculation**

3135 As mentioned in section B.2.1, the analysis of DAQ data provides the user with 3 CSV files and
 3136 a ROOT file associated to each and every ROOT data file. The fourth CSV file is provided by the
 3137 extraction of the CEAN main frame data monitored during data taking and will be discussed later.
 3138 After looping on the data in the previous part of the analysis macro, the output files are created and a
 3139 3D loop on each RPC readout partitions is started to extract the histograms parameters and compute
 3140 the final results.

3141

3142 **B.6.4.1 Rate normalisation**

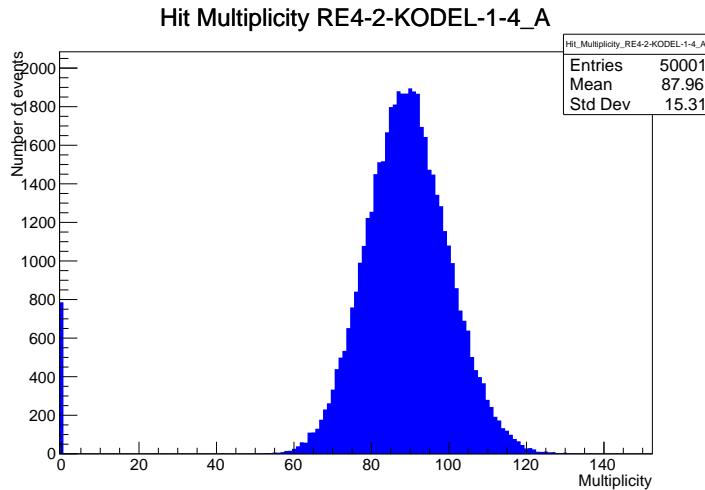

Figure B.2: The effect of the quality flag is explained by presenting the reconstructed hit multiplicity of a data file without `Quality_flag`. The artificial high content of bin 0 is the effect of corrupted data.

3143 To analyse old data format files, not containing any quality flag, it is needed to estimate the amount
 3144 of corrupted data via a fit as the corrupted data will always fill events with a fake "0 multiplicity".
 3145 Indeed, as no hits were stored in the DAQ ROOT files, these events artificially contribute to fill
 3146 the bin corresponding to a null multiplicity, as shown in Figure B.2. In the case the mean of the

hit multiplicity distribution is high, the contribution of the corrupted data can easily be evaluated for later correction by comparing the level of the bin at multiplicity 0 and of a skew fit curve that should indicate a value consistent with 0. A skew fit has been chosen over a Poisson fit as it was giving better results for lower mean multiplicity values. Nevertheless, for low irradiation cases, as explained in Appendix A.4.3, the hit multiplicity distribution mean is, on the contrary, rather small and the probability to record events without hits can't be considered small anymore, leading to a difficult and non-reliable estimation of the corruption. As can be seen in Source Code B.13, conditions have been applied to prevent bad fits and wrong corruption estimation in cases where :

- The difference in between the data for multiplicity 1 and the corresponding fit value should be lower than 1% of the total amount of data : $\frac{|n_{m=1} - sk(1)|}{N_{tot}} < 0.01$ where $n_{m=1}$ is the number of entries with multiplicity 1, $sk(1)$ the value of the skew fit, as defined by Formula 5.3, for multiplicity 1 and N_{tot} the total number of entries.

- The amount of data contained in the multiplicity 0 bin should not exceed 40% : $\frac{n_{m=0}}{N_{tot}} \leq 0.4$ where $n_{m=0}$ is the number of entries with multiplicity 0. This number has been determined to be the maximum to be able to separate the excess of data due to corruption from the hit multiplicity distribution.

Those 2 conditions need to be fulfilled to estimate the corruption of old data format files. If the fit was successful, the level of corruption is written in `Offline-Corrupted.csv` and the number of corrupted entries, refered as the integer `nEmptyEvent`, is subtracted from the total number of entries when the rate normalisation factor is computed as explicit in Source Code B.13. Note that for new data format files, the number of corrupted entries being set to 0, the definition of `rate_norm` stays valid.

```

3169   if(!isNewFormat){
      TF1* GaussFit = new TF1("gaussfit","[0]*exp(-0.5*((x-[1])/[2])**2)",0,Xmax);

```

Source Code B.13: Definition of the rate normalisation variable. It takes into account the number of non corrupted entries and the time window used for noise calculation, to estimate the total integrated time, and the strip active area to express the result as rate per unit area.

3172 B.6.4.2 Rate and activity

3173 At this point, the strip rate histograms, StripNoiseProfile_H.rpc[T][S][p], only contain an in-
 3174 formation about the total number of noise or rate hits each channel received during the data taking.
 3175 As described in Source Code B.14, a loop on the strip channels will be used to normalise the content
 3176 of the rate distribution histogram for each detector partitions. The initial number of hits recorded for
 3177 a given bin will be extracted and 2 values will be computed:

- 3178 ● the strip rate, defined as the number of hits recorded in the bin normalised like described in
 3179 the previous section, using the variable `rate_norm`, and

- 3180 ● the strip activity, defined as the number of hits recorded in the bin normalised to the average
 3181 number of hits per bin contained in the partition histogram, using the variable `averageNhit`.
 3182 This value provides an information on the homogeneity of the detector response to the gamma
 3183 background or of the detector noise. An activity of 1 corresponds to an average response.
 3184 Above 1, the channel is more active than the average and bellow 1, the channel is less active.

```

int nNoise = StripNoiseProfile_H.rpc[T][S][p]->GetEntries();
float averageNhit = (nNoise>0) ? (float)(nNoise/nStripsPart) : 1.;

for(Uint st = 1; st <= nStripsPart; st++) {
    float stripRate =
        StripNoiseProfile_H.rpc[T][S][p]->GetBinContent(st)/rate_norm;
    float stripAct =
        StripNoiseProfile_H.rpc[T][S][p]->GetBinContent(st)/averageNhit;

    StripNoiseProfile_H.rpc[T][S][p]->SetBinContent(st,stripRate);
    StripActivity_H.rpc[T][S][p]->SetBinContent(st,stripAct);
}

```

3186 *Source Code B.14: Description of the loop that allows to set the content of each strip rate and strip activity
 channel for each detector partition.*

3187 On each detector partitions, which are readout by a single FEE, all the channels are not processed
 3188 by the same chip. Each chip can give a different noise response and thus, histograms using a chip
 3189 binning are used to investigate chip related noise behaviours. The average values of the strip rate
 3190 or activity grouped into a given chip are extracted using the using the function `GetChipBin()` and
 3191 stored in dedicated histograms as described in Source Codes B.15 and B.16 respectively.

```

float GetChipBin(TH1* H, Uint chip){
    Uint start = 1 + chip*NSTRIPSCHIP;
    int nActive = NSTRIPSCHIP;
    float mean = 0.;

    for(Uint b = start; b <= (chip+1)*NSTRIPSCHIP; b++) {
        float value = H->GetBinContent(b);
        mean += value;
        if(value == 0.) nActive--;
    }

    if(nActive != 0) mean /= (float)nActive;
    else mean = 0.;

    return mean;
}

```

3194 *Source Code B.15: Function used to compute the content of a bin for an histogram using chip binning.*

```

3195   for(UInt ch = 0; ch < (nStripsPart/NSTRIPSCHIP); ch++) {
      ChipMeanNoiseProf_H.rpc[T][S][p]->
          SetBinContent(ch+1,GetChipBin(StripNoiseProfile_H.rpc[T][S][p],ch));
      ChipActivity_H.rpc[T][S][p]->
          SetBinContent(ch+1,GetChipBin(StripActivity_H.rpc[T][S][p],ch));
}

```

Source Code B.16: Description of the loop that allows to set the content of each chip rate and chip activity bins for each detector partition knowing the information contained in the corresponding strip distribution histograms.

The activity variable is used to evaluate the homogeneity of the detector response to background or of the detector noise. The homogeneity h_p of each detector partition can be evaluated using the formula $h_p = \exp(-\sigma_p^R / \langle R \rangle_p)$, where $\langle R \rangle_p$ is the partition mean rate and σ_p^R is the rate standard deviation calculated over the partition channels. The more homogeneously the rates are distributed and the smaller will σ_p^R be, and the closer to 1 will h_p get. On the contrary, if the standard deviation of the channel's rates is large, h_p will rapidly get to 0. This value is saved into histograms as shown in Source Code B.17 and could in the future be used to monitor through time, once extracted, the evolution of every partition homogeneity. This could be of great help to understand the apparition of eventual hot spots due to ageing of the chambers subjected to high radiation levels. The monitored homogeneity information could then be combined with a monitoring of the activity of each individual channel in order to have a finer information. Monitoring tools have been suggested and need to be developed for this purpose.

```

3209   float MeanPartSDev = GetTH1StdDev(StripNoiseProfile_H.rpc[T][S][p]);
   float strip_homog = (MeanPartRate==0)
     ? 0.
     : exp(-MeanPartSDev/MeanPartRate);
   StripHomogeneity_H.rpc[T][S][p]->Fill("exp -#left(#frac{\#sigma_{Strip}
     \rightarrow Rate}{\#mu_{Strip Rate}}\#right)",strip_homog);
   StripHomogeneity_H.rpc[T][S][p]->GetYaxis()->SetRangeUser(0.,1.);

3210   float ChipStDevMean = GetTH1StdDev(ChipMeanNoiseProf_H.rpc[T][S][p]);
   float chip_homog = (MeanPartRate==0)
     ? 0.
     : exp(-ChipStDevMean/MeanPartRate);
   ChipHomogeneity_H.rpc[T][S][p]->Fill("exp -#left(#frac{\#sigma_{Chip}
     \rightarrow Rate}{\#mu_{Chip Rate}}\#right)",chip_homog);
   ChipHomogeneity_H.rpc[T][S][p]->GetYaxis()->SetRangeUser(0.,1.);

```

Source Code B.17: Storage of the homogeneity into dedicated histograms.

3212 B.6.4.3 Strip masking tool

The offline tool is automatically called at the end of each data taking to analyse the data and offer the shifter DQM histograms to control the data quality. After the histograms have been published online in the DQM page, the shifter can decide to mask noisy or dead channels that will contribute to bias the final rate calculation by editing the mask column of `ChannelsMapping.csv` as can be seen in Figure B.3.

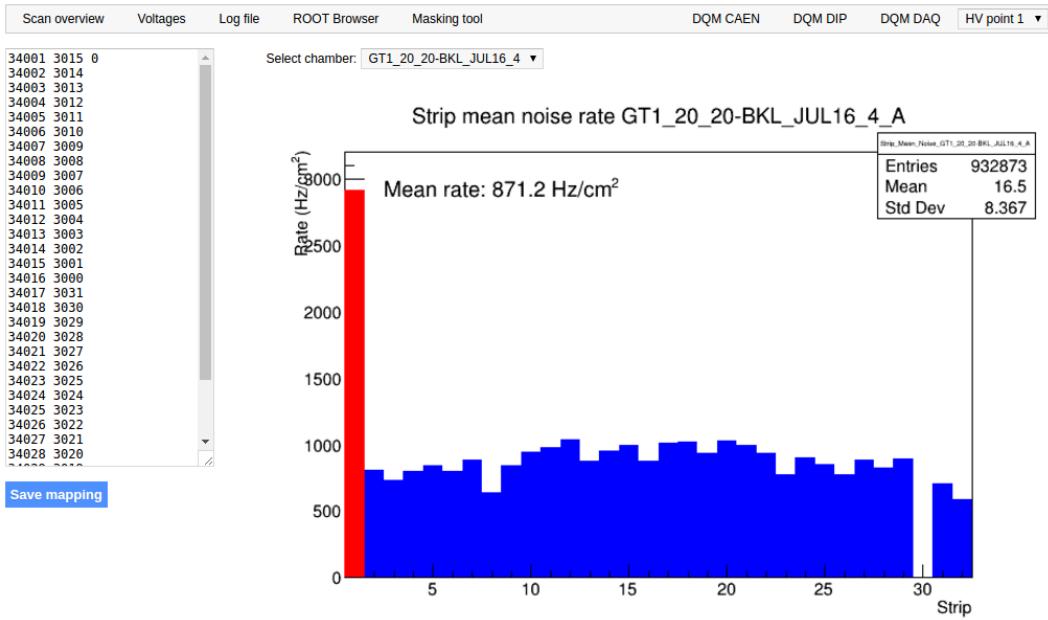

Figure B.3: Display of the masking tool page on the webDCS. The window on the left allows the shifter to edit ChannelsMapping.csv. To mask a channel, it only is needed to set the 3rd field corresponding to the strip to mask to 0. It is not necessary for older mapping file formats to add a 1 for each strip that is not masked as the code is versatile and the default behaviour is to consider missing mask fields as active strips. The effect of the mask is directly visible for noisy channels as the corresponding bin turns red. The global effect of masking strips will be an update of the rate value showed on the histogram that will take into consideration the rejected channels.

3218 From the code point of view, the function `GetTH1Mean()` is used to retrieve the mean rate par-
 3219 tition by partition after the rates have been calculated strip by strip and filled into the histograms
 3220 `StripNoiseProfile_H.rpc[T][S][p]`, as described through Source Code B.18.

3221 Once the mask for each rejected channel has been updated, the shifter can manually run the of-
 3222 fline tool again to update the DQM plots, now including the masked strips, as well the rate results
 3223 written in the output CSV file `Offline-Rate.csv`. If not done during the shifts, the strip masking
 3224 procedure needs to be carefully done by the person in charge of data analysis on the scans that were
 3225 selected to produce the final results.

```

3226   float GetTH1Mean(TH1* H) {
3227     int nBins = H->GetNbinsX();
3228     int nActive = nBins;
3229     float mean = 0.;
3230
3231     for(int b = 1; b <= nBins; b++) {
3232       float value = H->GetBinContent(b);
3233       mean += value;
3234       if(value == 0.) nActive--;
3235     }
3236
3237     if(nActive != 0) mean /= (float)nActive;
3238     else mean = 0.;
3239
3240     return mean;
3241   }

```

Source Code B.18: The function `GetTH1Mean()` is used to return the mean along the y-axis of `TH1` histograms containing rate information. In order to take into account masked strips whose rate is set to 0, the function looks for masked channels and decrement the number of active channels for each null value found.

3229 B.6.4.4 Output CSV files filling

3230 All the histograms have been filled. Parameters will then be extracted from them to compute the
 3231 final results that will later be used to produce plots. Once the results have been computed, the very
 3232 last step of the offline macro is to write these values into the corresponding CSV outputs. Aside of
 3233 the file `Offline-Corrupted.csv`, 2 CSV files are being written by the macro `offlineAnalysis()`,
 3234 `Offline-Rates.csv` and `Offline-L0-EffCl.csv` that respectively contain information about noise
 3235 or gamma rates, cluster size and multiplicity, and about level 0 reconstruction of the detector effi-
 3236 ciency, muon cluster size and multiplicity. Details on the computation and file writing are respec-
 3237 tively given in Sources Codes B.19 and B.20.

3238 **Noise/gamma background variables** are computed and written in the output file for each detector
 3239 partitions. A detector average of the hit and cluster rate is also provided, as shown through Sources
 3240 Code B.19. The variables that are written for each partition are:

- 3241 • The mean partition hit rate per unit area, `MeanPartRate`, that is extracted from the histogram
 3242 `StripNoiseProfile_H` as the mean value along the y-axis, as described in section B.6.4.3. No
 3243 error is recorded for the hit rate as this is considered a single measurement. No statistical error
 3244 can be associated to it and the systematics are unknown.
- 3245 • The mean cluster size, `cSizePart`, is extracted from the histogram `NoiseCSize_H` and it's
 3246 statistical error, `cSizePartErr`, is taken to be 2σ of the total distribution.
- 3247 • The mean cluster multiplicity per trigger, `cMultPart`, is extracted from the histogram `NoiseCMult_H`
 3248 and it's statistical error, `cMultPartErr`, is taken to be 2σ of the total distribution. It is impor-
 3249 tant to point to the fact that this variable gives an information that is dependent on the buffer
 3250 window width used for each trigger for the calculation.
- 3251 • The mean cluster rate per unit area, `ClustPartRate`, is defined as the mean hit rate normalised

3252 to the mean cluster size and it's statistical error, `ClustPartRateErr`, is then obtained using the
 3253 relative statistical error on the mean cluster size.

```

for (UInt tr = 0; tr < GIFInfra->GetNTrolleys(); tr++) {
  UInt T = GIFInfra->GetTrolleyID(tr);

  for (UInt sl = 0; sl < GIFInfra->GetNSlots(tr); sl++) {
    UInt S = GIFInfra->GetSlotID(tr,sl) - 1;

    float MeanNoiseRate = 0.;
    float ClusterRate = 0.;
    float ClusterSDev = 0.;

    for (UInt p = 0; p < GIFInfra->GetNPartitions(tr,sl); p++) {
      float MeanPartRate = GetTH1Mean(StripNoiseProfile_H.rpc[T][S][p]);
      float cSizePart = NoiseCSIZE_H.rpc[T][S][p]->GetMean();
      float cSizePartErr = (NoiseCSIZE_H.rpc[T][S][p]->GetEntries()==0)
        ? 0.
        : 2*NoiseCSIZE_H.rpc[T][S][p]->GetStdDev() /
          sqrt(NoiseCSIZE_H.rpc[T][S][p]->GetEntries());
      float cMultPart = NoiseCMult_H.rpc[T][S][p]->GetMean();
      float cMultPartErr = (NoiseCMult_H.rpc[T][S][p]->GetEntries()==0)
        ? 0.
        : 2*NoiseCMult_H.rpc[T][S][p]->GetStdDev() /
          sqrt(NoiseCMult_H.rpc[T][S][p]->GetEntries());
      float ClustPartRate = (cSizePart==0) ? 0.
        : MeanPartRate/cSizePart;
      float ClustPartRateErr = (cSizePart==0) ? 0.
        : ClustPartRate * cSizePartErr/cSizePart;

      outputRateCSV << MeanPartRate << '\t'
        << cSizePart << '\t' << cSizePartErr << '\t'
        << cMultPart << '\t' << cMultPartErr << '\t'
        << ClustPartRate << '\t' << ClustPartRateErr << '\t';

      RPCarea += stripArea * nStripsPart;
      MeanNoiseRate += MeanPartRate * stripArea * nStripsPart;
      ClusterRate += ClustPartRate * stripArea * nStripsPart;
      ClusterSDev += (cSizePart==0)
        ? 0.
        : ClusterRate*cSizePartErr/cSizePart;
    }

    MeanNoiseRate /= RPCarea;
    ClusterRate /= RPCarea;
    ClusterSDev /= RPCarea;

    outputRateCSV << MeanNoiseRate << '\t'
      << ClusterRate << '\t' << ClusterSDev << '\t';
  }
}

```

Source Code B.19: Description of rate result calculation and writing into the CSV output `Offline-Rate.csv`. Are saved into the file for each detector, the mean partition rate, cluster size and cluster mutiplicity, along with their errors, for each partition and as well as a detector average.

3256 **Muon performance variables** are computed and written in the output file for each detector partitions as shown through Sources Code B.20. The variables that are written for each partition are:

- 3258 ● The muon efficiency, `eff`, extracted from the histogram `Efficiency0_H`. It is reminded that
3259 this offline tool doesn't include any tracking algorithm to identify muons from the beam and
3260 only relies on the hits arriving in the time window corresponding to the beam time. The con-
3261 tent of the efficiency histogram is thus biased by the noise/gamma background contribution
3262 into this window and is thus corrected by estimating the muon data content in the peak re-
3263 gion knowing the noise/gamma content in the rate calculation region. Both time windows
3264 being different, the choice was made to normalise the noise/gamma background calculation
3265 window to it's equivalent beam window in order to have comparable values using the variable
3266 `windowRatio`. Finally, to estimate the data ratio in the peak region, the variable `DataRatio`
3267 is defined as the ratio in between the estimated mean cluster multiplicity of the muons in the
3268 peak region, `MuonCM`, and of the total mean cluster multiplicity in the peak region, `PeakCM`.
3269 `MuonCM` is itself defined as the difference in between the total mean cluster multiplicity in the
3270 peak region and the normalised mean noise/gamma cluster multiplicity calculated outside of
3271 the peak region. The statistical error related to the efficiency, `eff_err`, is computed using a
3272 binomial distribution, as the efficiency measure the probability of "success" and "failure" to
3273 detect muons.
- 3274 ● The mean muon cluster size, `MuonCS`, is calculated using the total mean cluster size and multi-
3275 plicity in the peak region, respectively extracted from histograms `MuonCSize_H` and `MuonCMult_H`,
3276 the noise/gamma background mean cluster size and normalised multiplicity, extracted from
3277 `NoiseCSize_H` and `NoiseCMult_H`, and of the estimated muon cluster multiplicity `MuonCM` pre-
3278 viously explicated. The associated statistical error, `MuonCM_err`, is calculated using the propa-
3279 gation of errors of the mentioned variables.
- 3280 ● The mean muon cluster multiplicity in the peak region, `MuonCM`, explicated above whose sta-
3281 tistical error, `MuonCM_err`, is the sum of statistical error associated to the total mean clus-
3282 ter multiplicity in the peak reagion, `PeakCM_err`, and of the mean noise/gamma cluster size,
3283 `NoiseCM_err`.

3284 In addition to these 2 CSV files, the histograms are saved in ROOT file `Scan00XXXX_HVY_Offline.root`
3285 as explained in section B.2.1.1.

Source Code B.20: Description of efficiency result calculation and writing into the CSV output Offline-L0-EffCl.csv. Are saved into the file for each detector, the efficiency, corrected taking into account the background in the peak window of the time profile, muon cluster size and muon cluster multiplicity, along with their errors, for each partition and as well as a detector average.

3288

3289 B.7 Current data Analysis

3290 Detectors under test at GIF++ are connected both to a CAEN HV power supply and to a CAEN
3291 ADC that reads the currents inside of the RPC gaps bypassing the supply cable. During data tak-
3292 ing, the webDCS records into a ROOT file called `Scan00XXXX_HVY_CAEN.root` histograms with the
3293 monitored parameters of both CAEN devices. Are recorded for each RPC channels (in most cases,
3294 a channel corresponds to an RPC gap):

- 3295 • the effective voltage, HV_{eff} , set by the webDCS using the PT correction on the CAEN power
3296 supply,
- 3297 • the applied voltage, HV_{app} , monitored by the CAEN power supply, and the statistical error
3298 related to the variations of this value through time to follow the variation of the environmental
3299 parameters defined as the RMS of the histogram divided by the square root of the number of
3300 recorded points,
- 3301 • the monitored current, I_{mon} , monitored by the CAEN power supply, and the statistical error
3302 related to the variations of this value through time to follow the variation of the environmental
3303 parameters defined as the RMS of the histogram divided by the square root of the number of
3304 recorded points,
- 3305 • the corresponding current density, J_{mon} , defined as the monitored current per unit area,
3306 $J_{mon} = I_{mon}/A$, where A is the active area of the corresponding gap,
- 3307 • the ADC current, I_{ADC} , recorded through the CAEN ADC module that monitors the dark
3308 current in the gap itself. First of all, the resolution of such a module is better than that of
3309 CAEN power supplies and moreover, the current is not read-out through the HV supply line
3310 but directly at the chamber level giving the real current inside of the detector. The statistical
3311 error is defined as the RMS of the histogram distribution divided by the square root of the
3312 number of recorded points.

3313 Once extracted through a loop over the element of GIF++ infrastructure via the C++ macro
3314 `GetCurrent()`, these parameters, organised in 9 columns per detector HV supply line, are written in
3315 the output CSV file `Offline-Current.csv`. The macro can be found in the file `Current.cc`.
